

Frogs

## Allophrynidae

3 species in 1 genus

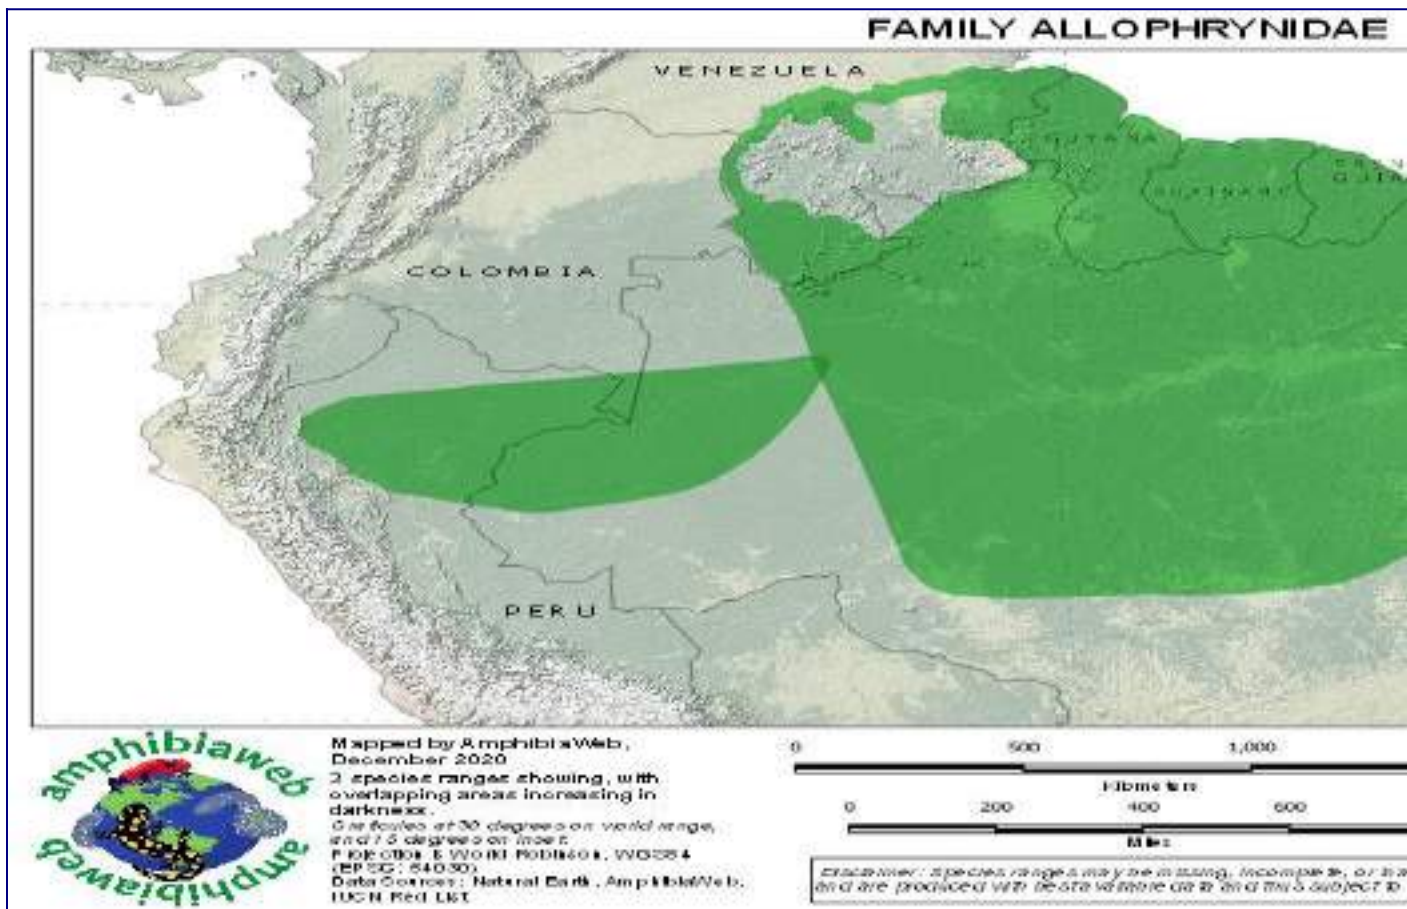

***Commonly Called* Tukeit Hill Frog, Resplendent Frog**

A monotypic family whose position within "Neobatrachia" has been an enigma since its discovery by Gaige (1927) and has been collected in Venezuela, Suriname, Guyana, French Guiana, and Brazil. Recent studies (see species list) place it in the Centrolenidae. Not much is known about this family's ecology, behavior, or development.

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Found in shrubby, vegetated habitat associated with streams
- Morphological characters for this family include: 1) eight presacral vertebrae; 2) ribs absent; 3) urostyle present; 4) girdle arciferal; 5) sternum cartilaginous and omosternum absent; 6) clavicle does not overlie scapula; 7) intercalary cartilage between final and penultimate phalanx; 8) sartorius muscle separate and distinct from iliofibularis; 9) 10) T-shaped terminal phalanges
- Tadpoles are aquatic and Type IV
- Some species are nocturnal
- Distribution limited to Guyanan region of South America

# Alsodidae

26 species in 3 genera

## ***Commonly Called Spiny-chest Frogs, Ground Frogs, or Rapids Frogs***

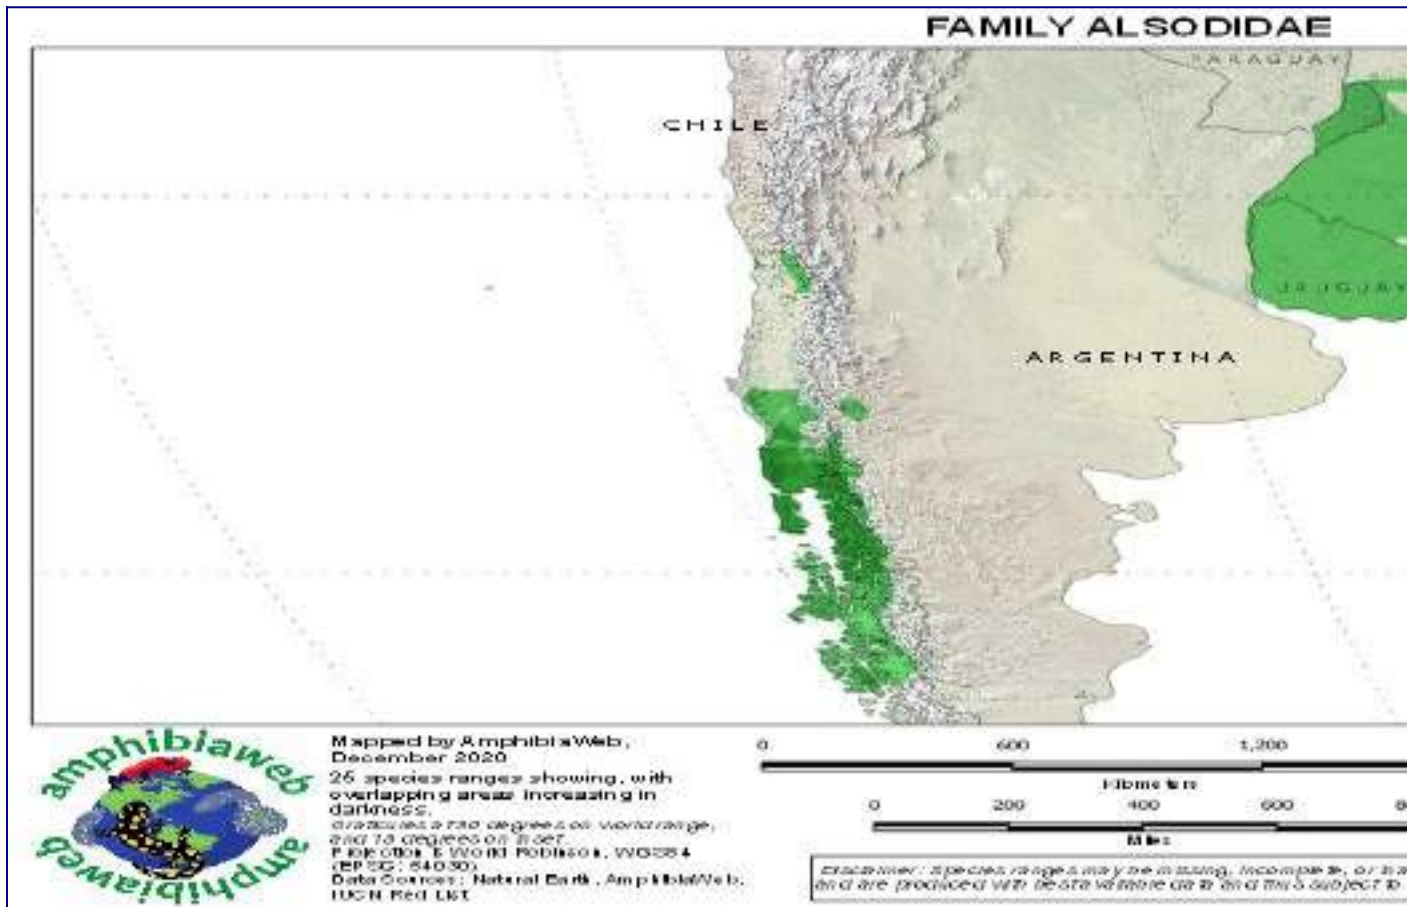

Generally a family of small to medium (25- 70 mm snout-vent length), yellow, brown or reticulated frogs from forests or rivers; some are found in high-altitude grasslands. Most species of this family are poorly known.

Alsodidae was first recognized by Pyron and Wiens (2011) when their molecular analysis could not support the family as monophyletic. Subsequently Blotto et al (2013) could not support *Limnomedusa* within Alsodidae so its inclusion was rejected.

Written by AmphibiaWeb

## **Notable Family Characteristics**

- Tadpoles are free-swimming in ponds and pools
- Found in forests, rivers, and some in arid regions
- Males of *Alsodes* develop discrete patches of spines on their chest and spiny protuberances on their throat during breeding season
- Distribution limited to South America, in regions of Patagonia, southern Brazil and the Andes.

## Aromobatidae

146 species in 6 genera

## **Commonly Called Cryptic Forest Frogs, Cryptic Poison Frogs**

*Allobates femoralis*

Photo by Alessandro Cate

[\(Click for family gallery\)](#)

Native to Central and South America, the Aromobatidae are cryptic, forest floor dwelling frogs and are sister to the colorful Poison Dart frog family Dendrobatidae. The species in this family were considered subfamilies of Dendrobatidae (Allobatinae, Anomaloglossinae, and Aromobatinae) until its recognition in 2006 by Grant et al. as a separate family. Blackburn and Wake (2011) in their survey of taxonomy no longer recognize these subfamilies.

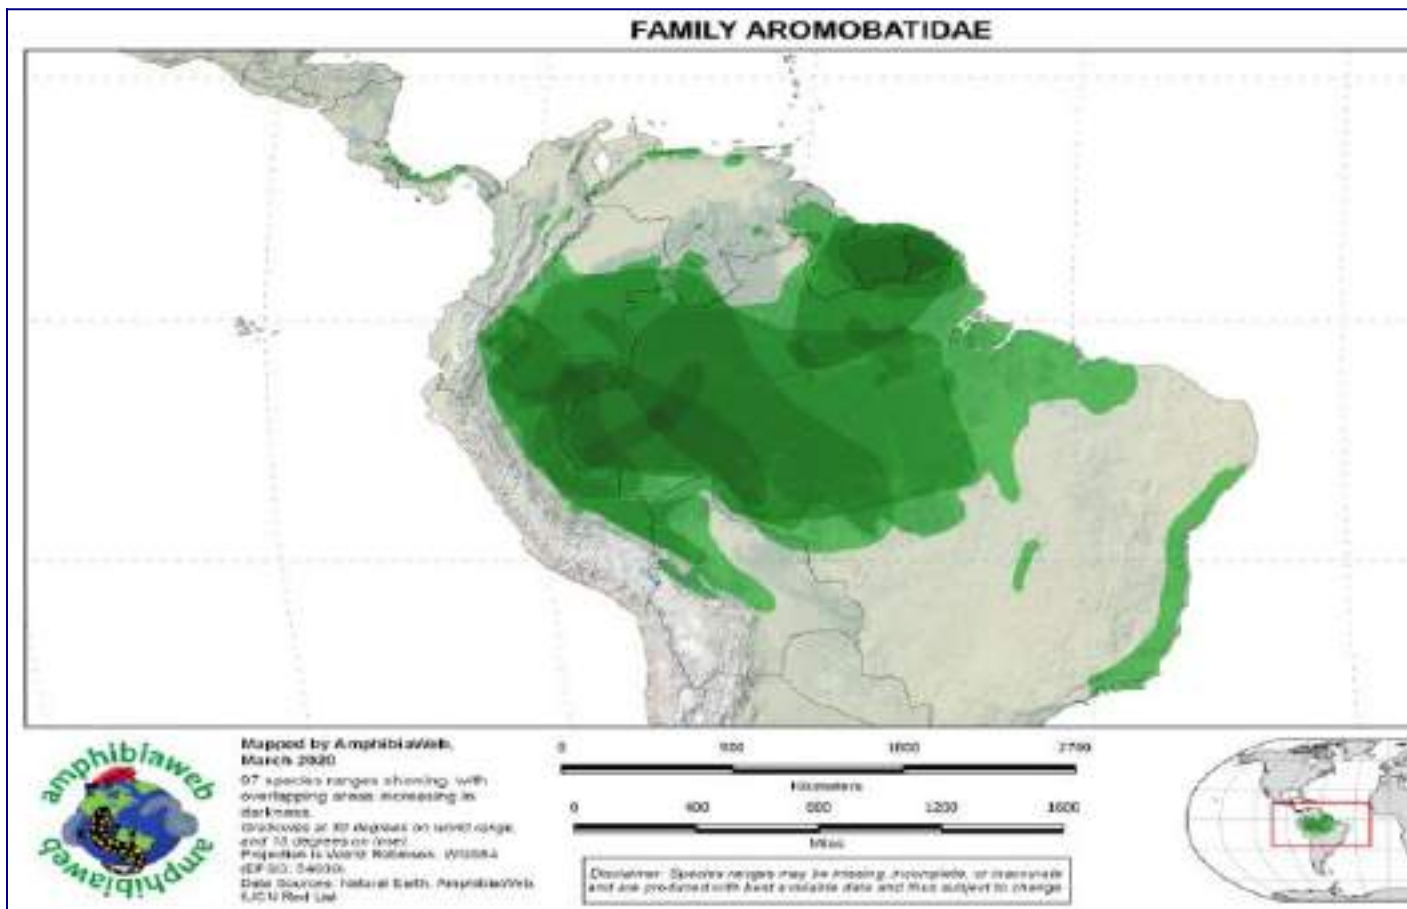

In contrast to its sister clade, aromobatids are cryptically colored and lack toxic skin alkaloids. Most species deposit clutches of eggs and display a high degree of parental care such as transporting tadpoles between water sources (e.g., streamside pools, bromeliads, and leaf nests) or may lay trophic eggs to feed tadpoles. Many species are also known for social behaviours such as males calling to defend territories or scarce resources such as ideal egg deposition and rearing sites. Males may call throughout the day.

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Mostly diurnal, with one known exception
- Lack ability to sequester alkaloids in the skin (unlike sister clade Dendrobatidae). Some are known for their noxious odor.
- Eggs are laid, hatch into tadpoles, and cared for by parents. Some have endotrophic tadpoles, which develop into froglets
- Males may call and defend territories, such as limited egg deposition and tadpole-rearing sites
- Morphological characters include moderate to extensive toe webbing
- Distribution limited to the neotropical rainforests of Central and South America

# Arthroleptidae

154 species in 8 genera

**Commonly Called Squeaker Frogs, Long-fingered Frogs, Night Frogs, Egg Frogs, Hairy Frogs, Forest Frogs, African "Big-eyed" Treefrogs**

These African genera were once considered part of the large Ranidae family, but have been shown to be sister to the Ranidae (and thus a new family, the Arthroleptidae). None of the Arthroleptidae are found on oceanic islands, with the single exception of *Leptopelis palmatus*. The Arthroleptidae and Hyperoliidae are part of a larger radiation that is restricted to sub-Saharan Africa, which also includes the Microhylidae (formerly included as a subfamily of the Microhylidae). Within the Arthroleptidae, subfamily taxonomy is still in flux due to a wide range of morphology, ecology, body sizes, and life history. All of these genera can be found in forests, but *Leptopelis* is also found in moist grasslands. Members of some other genera are sometimes found in moist high-altitude grasslands.

All genera have tadpoles, except *Arthroleptis* and possibly a few *Leptopelis* species which have direct development in small pools. Adults and tadpoles of *Astylosternus*, *Trichobatrachus*, and *Leptodactylodon* are eaten by local predators.

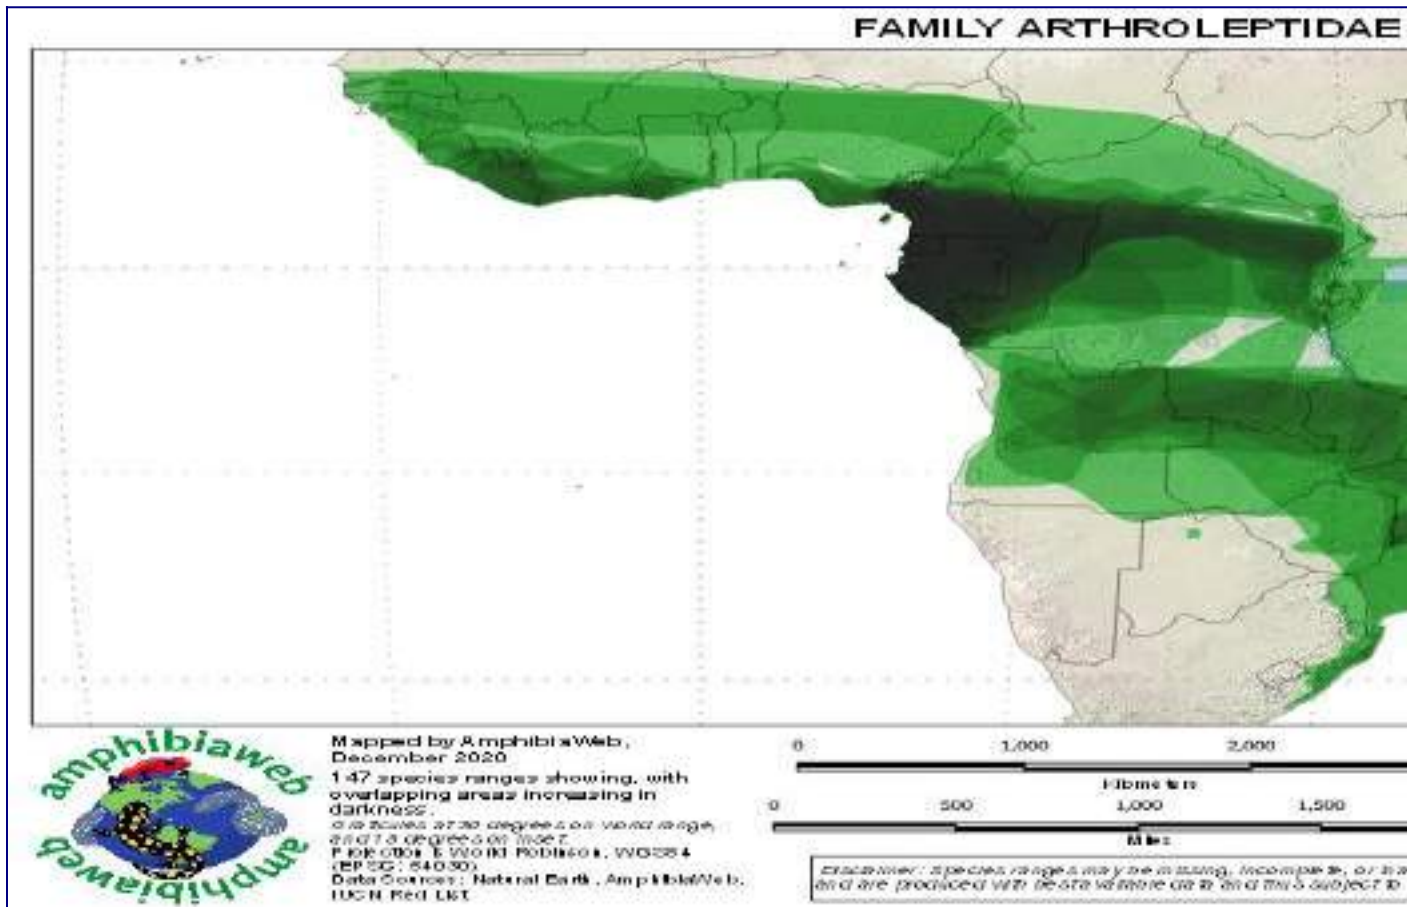

The Hairy Frog (*Trichobatrachus robustus*) is the most famous of the arthroleptid species, due to breeding male skin extensions. These extensions are believed to aid in cutaneous respiration.

Written by David Blackburn, University of Kansas.

## Notable Family Characteristics

- Generally small frogs (less than 40 mm snout-vent length)
- Most genera have tadpoles (exceptions are *Arthroleptis* and possibly a few *Leptopelis* species, which have direct development)
- Unlike ranids, of which they were once considered, arthroleptids have cartilaginous sterna, (ossified in ranids)
- Found in forest leaf-litter; *Leptopelis* and *Arthroleptis* can also be found in woodlands and moist grasslands
- Distribution limited to Sub-Saharan Africa

## Ascaphidae

2 species in 1 genus

## ***Commonly Called Tailed Frogs***

The most striking feature of Tailed Frogs is its namesake or "tail", which is actually the external copulatory organ used for fertilization that takes place underwater in fast flowing streams. The copulatory organ is controlled by the same muscle, the *caudalipuboischiotibialis* (this muscle is only found in this family among frogs). Tadpoles have large sucker-like mouths with which they feed. Tadpoles may take up to 7 years to metamorphose, although 4 is average. They are small, brown or black, and do not vocalize.

Ascaphids are considered primitive frogs whose closest sister-group is Leiopelmatidae.

These species inhabit cold, fast flowing streams from British Columbia, south to Mendocino County (California) in North America.

Written by AmphibiaWeb

### **Notable Family Characteristics**

- They are unique in having an external copulatory organ, which gives its name "Tailed Frogs"
- Fertilization is internal taking place underwater
- Tadpoles have large sucker-like mouths and live in fast-flowing streams
- Tadpoles take an average of 4 years, up to 7, to metamorphose
- Inhabits cold, fast-flowing streams, as adults and tadpoles
- Some morphological features: 1) 9 presacral vertebrae; 2) sternum cartilaginous, omosternum present; 3) no condyle; 4) free ribs present on 3rd, 4th, and 5th vertebrae; 5) pectoral girdle arciferal; 6) clavicle overlying the scapula; 7) premaxillae contain teeth; 8) sartorius not a separate muscle; 9) aquatic larvae (Type III); 10) presence of the caudalipuboischiotibialis muscle; 11) tympanum absent; 12) pupil vertically elliptical
- Distribution limited to Pacific Northwest and Rocky Mountains of North America

**13 species in 4 genera**

***Commonly Called Patagonia Frogs, South American Wood Frogs, or Emerald Forest Frogs***

These medium-sized frogs are restricted to the southern region of South America. Formerly a subfamily of *Certhophryninae*.

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Medium-sized frog, up to about 60 mm SVL
- Axillary amplexus
- At least two types of tadpoles are known from one species *Atelognathus patagonicus*: an aquatic type and a littoral type, which lives at deeper depths lacking skin folds (Cuervo et al 2006)
- Known from high elevations, especially *Chaltenobatrachus grandisonae* most often found from 500 to 1000 m
- Distribution limited to South America, southern Chile through southwestern Argentina

## Bombinatoridae

10 species in 2 genera

***Commonly Called Yellow-Bellied Toads, Fire-Bellied Toads, Flat-Headed Toads***

This family is composed of the two genera *Barbourula* and *Bombina*. *Barbourula* is found in the Philippines and are very secretive and active at night. These are small aquatic toads that lay eggs and vocalize during inha

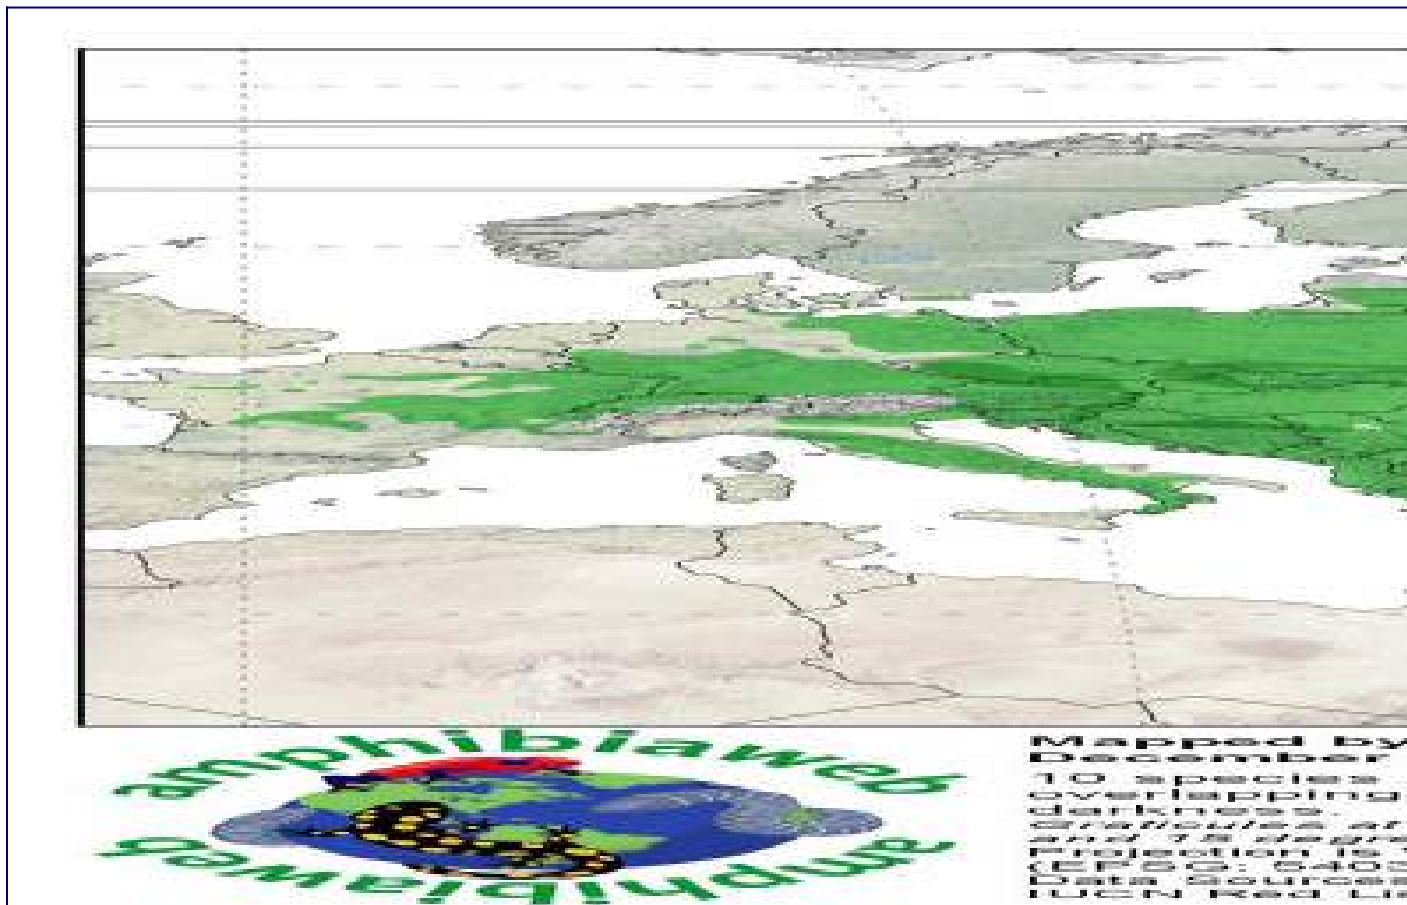

The only known lungless frog is a bombinatorid, *Barbourula kalimantanensis*, the Bornean Flat-headed Frog.

Written by AmphibiaWeb

### Notable Family Characteristics

- Inhabits ponds, slow-moving waters, and associated submersive vegetation or rocky shores
- Aquatic
- *Bombina* has brightly colored venters, likely as a warning coloration
- Most likely diurnal
- Displays "unken reflex" when threatened (*Bombina*)

- Vocalizes on inhalation
- Morphological characters for this group are: 1) halves of sphenethmoid fused; 2) absence of palatines
- Distribution limited to Europe, and also Asia, specifically southern China through the Korean Peninsula

## Brachycephalidae

84 species in 2 genera

### Commonly Called Robber Frogs, Three-Toed Toadlets

This family is an assemblage of direct-developing frogs from Brazil and northern Argentina, and is composed of two genera, *Brachycephalus* and *Ischnocnema*. The family Brachycephalidae is defined primarily by molecular characters. No unique morphological characters are shared by these genera. Members of this family range in size from 10.2 mm snout-vent length in females of *Brachycephalus didactylus* to 54 mm in females of *Ischnocnema guentheri*.

Frogs of the genus *Brachycephalus* are known as "Saddle-back Toads," due to the presence of bony shields above the vertebrae, or "Pumpkin Toads," from the bright orange coloration of some of the members of this family. At first they were considered to be Bufonids, but absence of a Bidder's organ (ovarian tissue on the testes, a synapomorphy of Bufonidae) led to their recognition as an independent family. Due to their small size and large genomes (an ancestral characteristic), these frogs have "lost" some of their digits (2 on the hand and 3 or 4 on the feet). These frogs are direct-developers with inguinal or axillary amplexus. *Brachycephalus ephippium* is known to possess tetrodotoxin, a toxin also found in newts of the genus *Taricha* and in puffer fish.

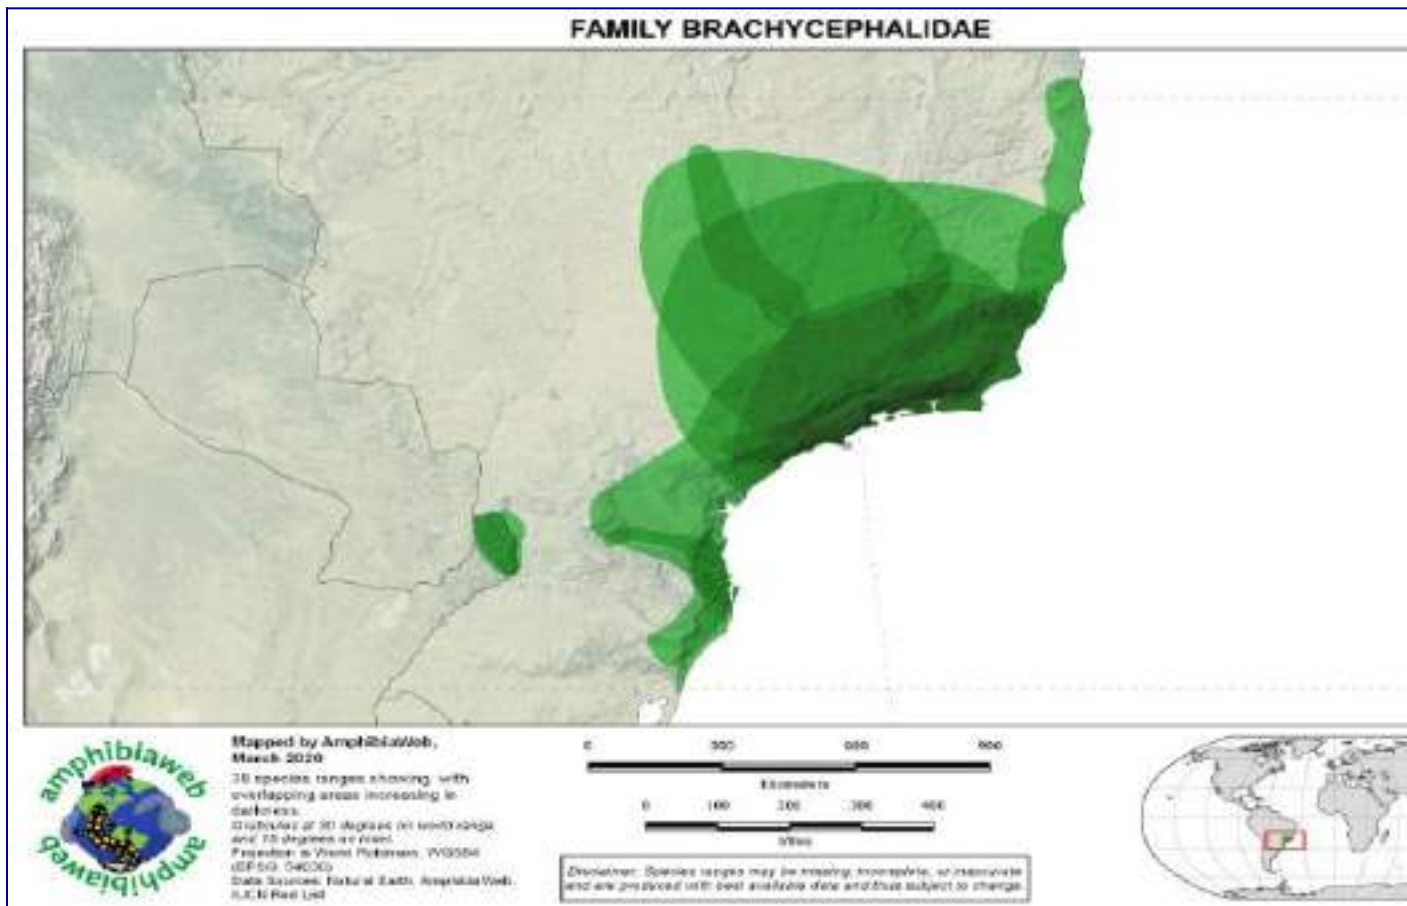

Frogs of the genus *Ischnocnema* are found throughout the Atlantic Coastal Forest in eastern Brazil, and in the Atlantic forest in extreme southeastern Brazil and northern Argentina.

Written by AmphibiaWeb

### Notable Family Characteristics

- Inhabits leaf litter in tropical rainforests, some are arboreal

- Direct development
- Amplexus may either be inguinal or axillary or shifting between the two
- Generally diurnal
- Distribution limited to South America

## Brevicipitidae

37 species in 5 genera

### *Commonly Called Rain Frogs*

*Breviceps*  
Photo by Thomas  
([Click for](#)

Previously considered as part of the Microhylidae, there is now strong support that the five genera comprising Brevicipitidae, following Frost et al. (2006), are part of a larger lineage of African frogs including the Hemisotidae and Brevicipitidae. Several studies confirm Brevicipitidae is the sister group of Hemisotidae.

All Brevicipitids are rounded in body and exhibit reductions in their skull. *Breviceps* is notable for its extreme male and female body sizes. Male frogs are so much smaller and have such short limbs relative to their volume that they cannot amplex. Instead, they have an adhesive secretion from the skin that allows males and females to "stick" together. Roughly spherical clutches of eggs are deposited in subterranean chambers. All five genera are believed to have direct development in which fully metamorphosed young hatch directly from eggs.

Brevicipitids are restricted to the eastern and southern parts of sub-Saharan Africa, from Ethiopia south to Angola and South Africa.

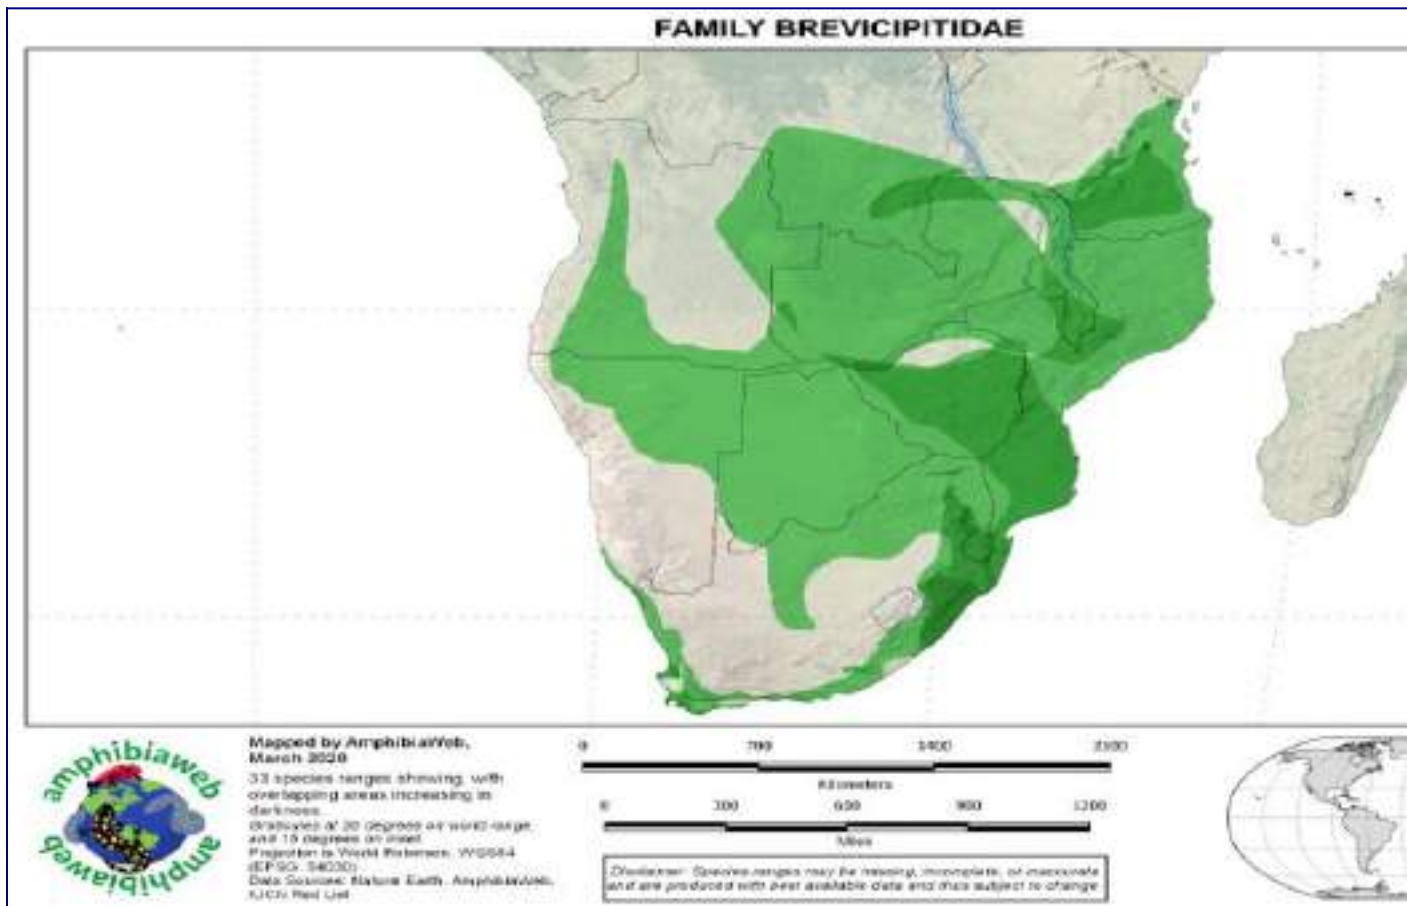

Written by David Blackburn and AmphibiaWeb

### Notable Family Characteristics

- Terrestrial and fossorial
- Found in forests and desert habitats
- Direct development
- Many species inflate their body when perturbed

- Characters uniting this clade include: (1) lack of ossified sphenethmoids; (2) an extremely short head; (3) middle ear absent.
- Distribution limited to the sub-Saharan Africa, from Ethiopia south to Angola and South Africa

## Bufonidae

666 species in 55 genera

### *Commonly Called True Toads*

This is a large and complicated assemblage. The family Bufonidae is composed of 52 genera with a worldwide distribution. One of the most notorious is the introduced Cane Toad (*Rhinella marina*), which has become a pest and danger to local wildlife, due to its toxicity (it has pronounced negative effects on native Australian snakes).

This family includes the stereotypical "toad" with shortened forelimbs, hindlimbs used for walking or hopping. Development in this group is quite varied; there are species that lay eggs in water and produce aquatic larvae, and there are species of frogs, *Nectophrynoides* and *Nimbaphrynoides occidentalis*, which give birth to fully developed young.

Bufonids have potent skin toxins, some concentrated in the prominent parotoid gland behind the eyes, and can be used for powerful potential pharmaceutical uses of these bufonid compounds, from both folk medicinal practices and modern medicine.

Some genera, like members of *Atelopus*, lack a tympanum and the middle ear column, making them "earless" (Smith, 2018), leaving many questions about their physiology and evolution.

Some toad species are believed to be extinct, including the famous Golden Toad (*Incilius periglenes*) of Costa Rica. Extinct by IUCN include *Atelopus longirostris* and *Atelopus vogli*.

This specious group has been subject to many phylogenetic studies over the years, some taking a comprehensive approach to the family, and others focusing on specific clades in attempts to propose a supported monophyletic taxonomy for bufonids. However, the diversity of over 600 species has not reached a consensus.

## News Highlights:

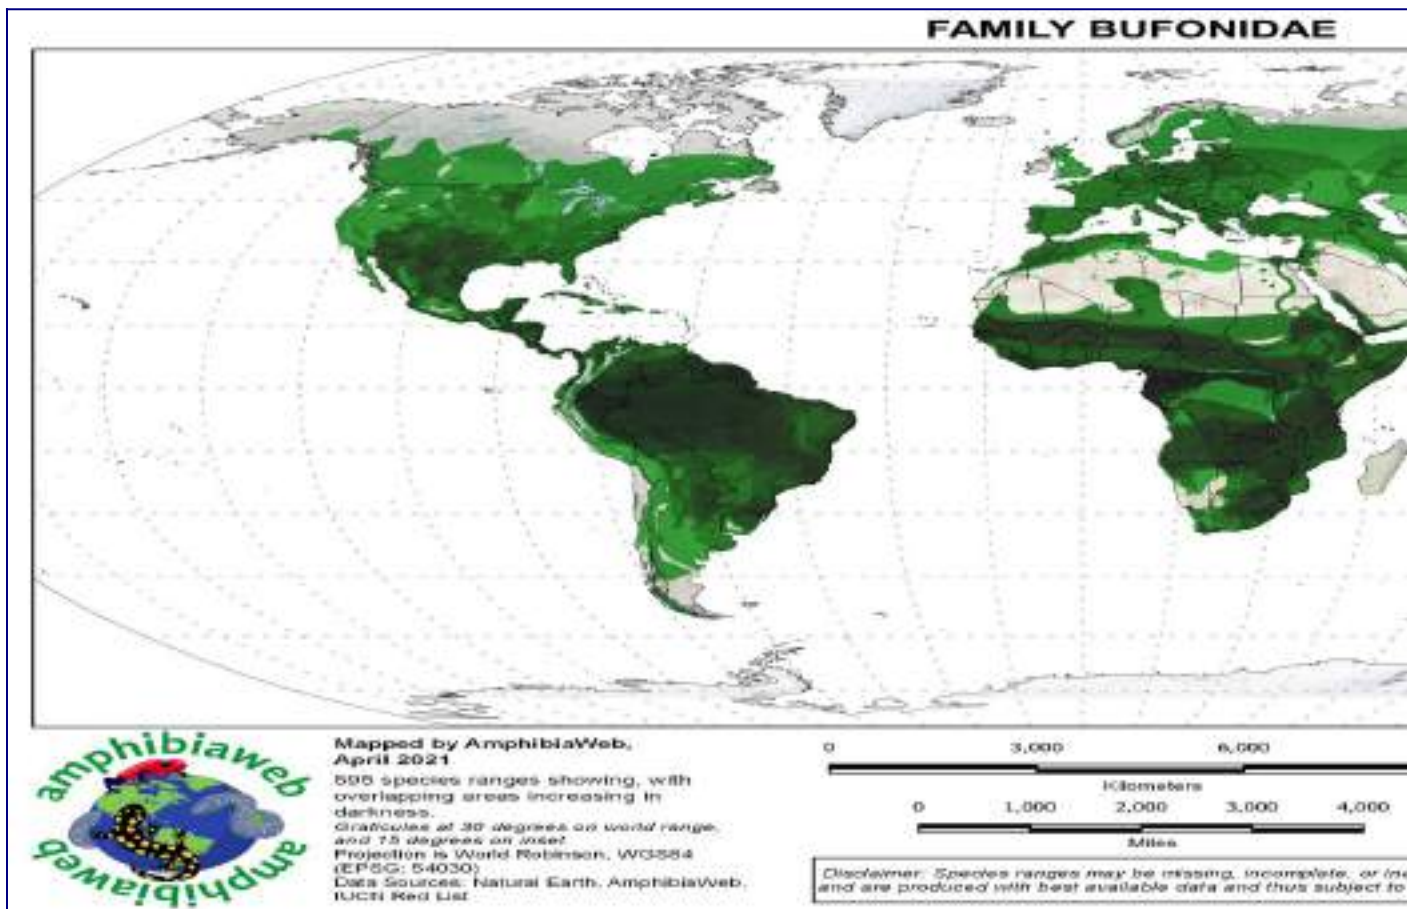

February 28, 2022: Harlequin toads (*Atelopus*) are renowned for their toxicity, but how much is really k characteristics? [Pearson and Tarvin \(2022\)](#) review *Atelopus* chemical defense literature and find that on toxins. Furthermore, South American species – which make up the vast majority of *Atelopus* diversity – to Central American species. Surveyed *Atelopus* possess individual toxins (chiriquitoxin and zetekitoxin the authors suggest that the genus contains further unidentified toxin diversity that – in the face of catas authors also trace the development of toxin detection and quantification methods applied to *Atelopus*, ne chemical defense data and identifying promising techniques for future studies. Lastly, given the limited speculate about possible immunological and ecological roles of *Atelopus* toxins. Time to study many ha make the case for continued chemical defense research on this genus. (Kannon Pearson)

February 15, 2021: The mystery of anuran middle ear loss has new insights! Most frogs have a tympani help them hear airborne sound. Despite being well known for their calls, many frogs and toads are “earl factors contributing to more than 38 evolutionary losses of the anuran ear remain unknown. Recently, [S species and two closely-related eared toad species. To their surprise, they found the middle ear column s species! However, in earless species, the middle ear column abruptly arrests development and remains e This means that the genetic and developmental mechanisms that initiate middle ear differentiation are in expression of biochemical pathways that regulate the extension or differentiation of the columella after lineages. Earless frogs are helping biologists understand the evolutionary and developmental mechanis further shows that lost traits are often not lost entirely. Their findings join many other studies that have r reviewed by \[Sadier et al. 2021\]\(#\). Studying development reveals key insights into evolutionary processes a](#)

Written by AmphibiaWeb

## Notable Family Characteristics

- Occurs in a variety of habitats, from deserts to tropical rainforests
- Reproductive modes vary from egg-laying in water bodies which hatch into free-living tadpoles to direct ovoviviparity to viviparity
- Some species display sexual dimorphism (such as larger females) or sexual dichromatism (such as mo during breeding season)
- Characters shared within the family are: 1) Bidder's organ present; 2) teeth absent from upper and low constrictor posterior muscle absent; 4) depressor mandibulae muscle originating solely from the squan fat bodies present; 6) skull highly ossified (usually skin is ossified to the skull).
- Distribution is worldwide, except for Australia, Oceania, where the Marine Toad *Rhinella marina* have

## Caligophrynidae

1 species in 1 genus

Known only from the elevated mountain (tepui) called the Neblina massif in northern

Brazil, the family Caligophrynidae was described in 2023 by Fouquet et al. The sole member species is distinguishable from its sister family Brachycephalidae mostly on the basis of molecular characters (Fouquet et al 2023). They state that there are no set of synapomorphies for this family but rather the unique combination of phenotypic characters which distinguish this family.

This family represents an ancient lineage of frogs known only from an isolated massif which Fouquet et al (2023) characterize as 'museums' or evolutionary refugia for "the diversification of Brachycephaloidea and of Neotropical biotas more broadly, in line with the influential 'Plateau theory' or 'Lost World Theory' (named after Sir Arthur Conan Doyle's famous story of the same name). This postulates that fragmented areas of repeated geographic, climatic, or other environmental isolation over long periods of time may favor allopatric speciation and maintain lineages through time.

Written by AmphibiaWeb

### Notable Family Characteristics

- Currently monotypic with one known species
- All known specimens found above 2,000 m asl on Neblina massif in Brazil in open grassy habitat
- An individual observed guarding a clutch of eggs in 1984 provides evidence of direct development and possible parental care in *Caligophryne doylei*

## Calyptocephalellidae

5 species in 2 genera

## ***Commonly Called* Helmeted Water Toads, False Toads**

*Calyptocephalella*

Photo by Peter

[\(Click for family page\)](#)

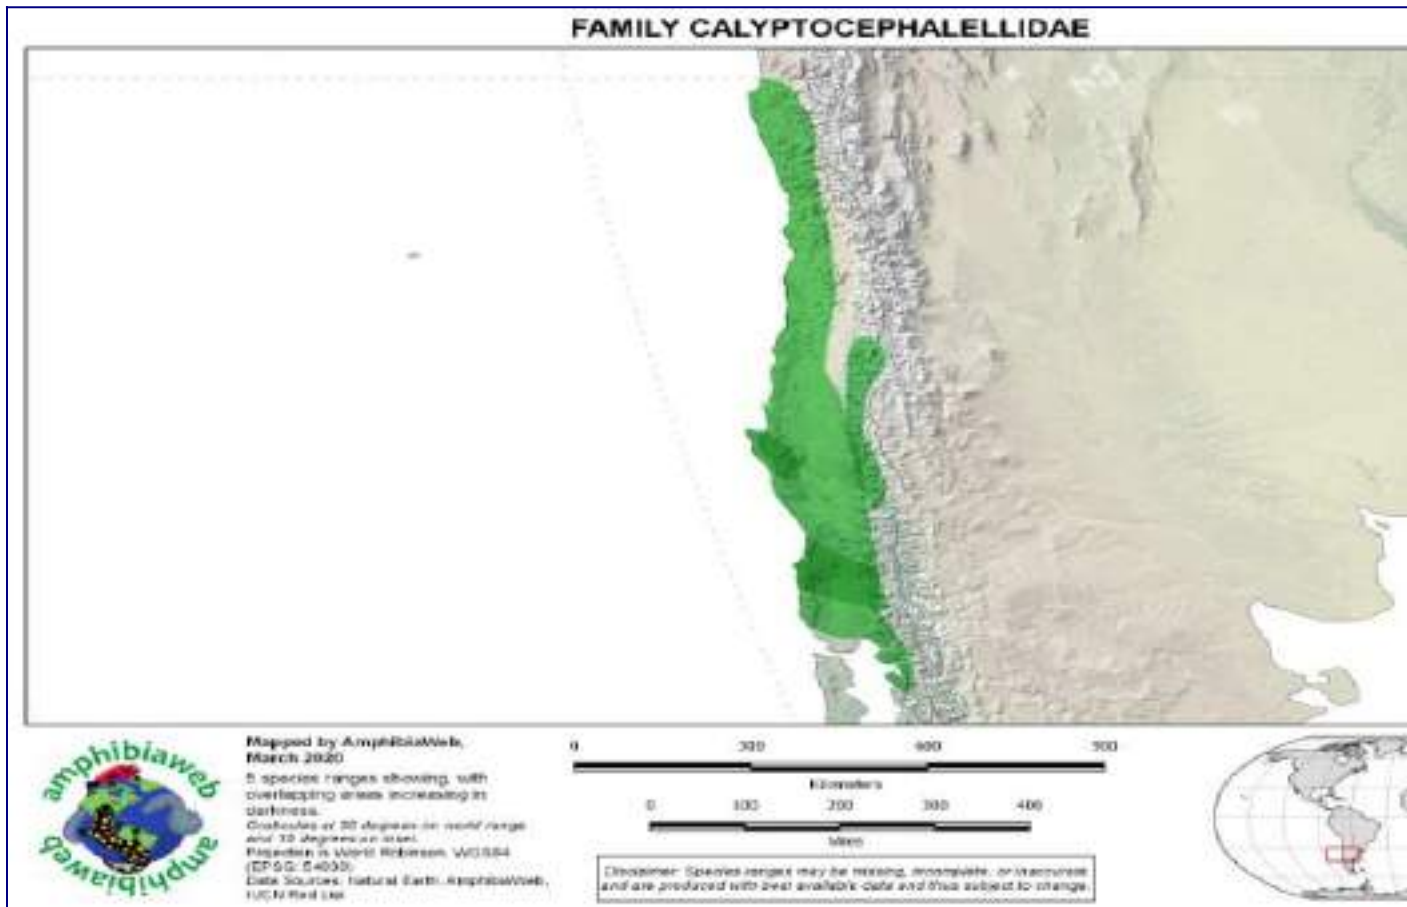

The family Calyptocephalellidae is confined to Chile, and contains two genera, *Calyptocephalella* and *Telmatobufo*. *Calyptocephalella gayi*, the Helmeted Water Toad, is the sole species within its genus and was formerly known as *Notthofagus caudiverbera*. Helmeted Water Toads are large, aquatic frogs, with females reaching up to 320 mm snout-vent length. Members of the genus, *Telmatobufo*, are smaller species and live in or next to fast-flowing streams in temperate forests.

This family has undergone taxonomic revision since it was originally named Batrachophrynidae (Frost et al. 2006) and was later to be renamed to Calyptocephalellidae (Frost 2007) when it was realized that prior karyotypic work by Córdova and Descailleaux (2005) had suggested that the genus *Batrachophrynus* was actually aligned with *Telmatobius* and the family Ceratophryidae. Subsequent analyses support *Calyptocephalella* and *Telmatobufo* as sister groups.

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Aquatic
- Aquatic tadpoles; *Telmatobufo* tadpoles live in fast-moving streams and have oral suction discs
- Robust, toadlike body
- Sexual dimorphism in *Calyptocephalella* where females are larger (up to 320 mm snout-vent length) than males (up to 120 mm)
- Axillary amplexus
- Distribution limited to mountains of Chile in South America

## Centrolenidae

171 species in 12 genera

### Commonly Called Glass Frogs

Centrolenid frogs derive their common name from the transparent ventral skin, through which internal organs are visible. The skin is green, ranging from light lime green to dark green. Members of this family also have green bones as a result of a unique pigment in their skin that reflects the same wavelength infrared radiation that plants do, possibly another adaptation (snout-vent length) with one exception, *Centrolene geckoideum*, which attains a length of 77 mm. Eggs are usually guarded by territorial males. The larvae drop into the water upon hatching and burrow in the sand.

Species of this group occur from Central America south through Venezuela, Bolivia, Argentina, and southern Brazil.

#### News Highlight

October 23, 2017: Parental care in frogs is a fascinating, yet understudied facet of amphibian behavioral ecology. [Delia et al. \(2017\)](#) recently explored the functional dynamics, sex-role characteristics, and evolutionary patterns of parental care in Centrolenidae. Their integrative study of 40 species combined behavioral field observations, maternal care experiments, and comparative phylogenetic methods to both elucidate patterns of care, and analyze the evolution of care across species, including eight for which care has never been documented. The care-giving sex was variable across species, rather than no care-to-male care transitions, male care evolved two to three times from female-only care. Brooding was associated with male care state transitions.

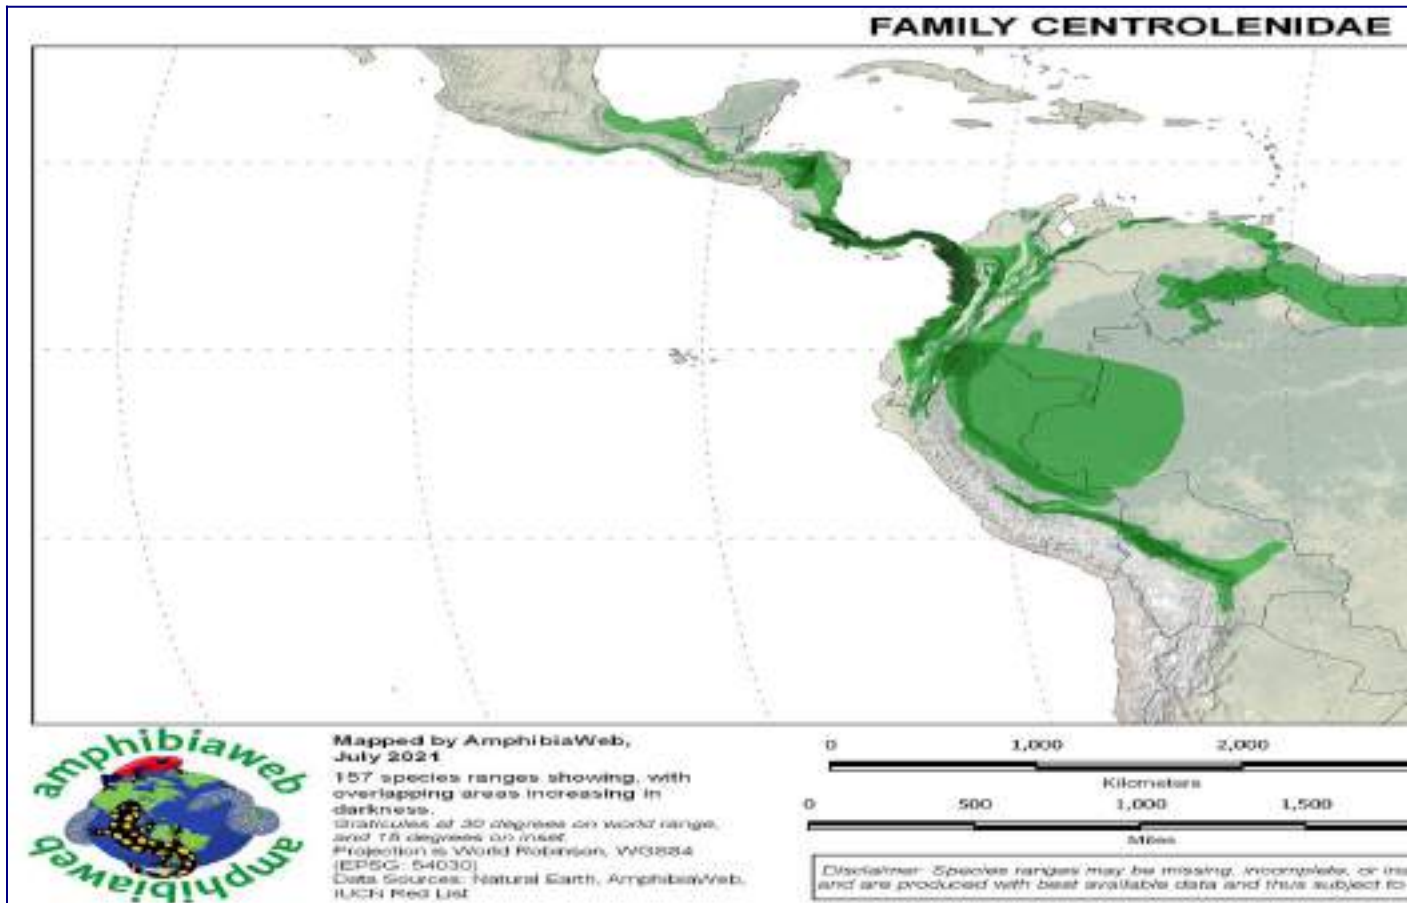

January 25, 2016: Parental care in anurans usually takes the form of attendance of eggs. Male attendance is observed in two genera of the glass frogs, family Centrolenidae: within *Centrolene* and within *Hyalinobatrachium*. In a third clade of centrolenids, *Ikakogi tayrona*, the geographic location (Sierra Nevada de Santa Marta, Colombia) is unique among centrolenids. Unexpectedly, the attendance in *Ikakogi tayrona* is by females. Care functions are similar to male care, but risk-tolerant, probably reflecting the more direct link to fitness in females. (DW)

Written by AmphibiaWeb

### Notable Family Characteristics

- Inhabits wet montane rainforests

- Eggs are deposited on leaves, in some species overhanging water into which hatched tadpoles fall
- Some form of parental care, from males and/or females, exhibited
- Many species are known for their territoriality, and males will fight each other; some species have human-like
- Morphological characters uniting this clade are: 1) astragalus and calcaneum completely fused (convergent with other groups); 2) process on third metacarpal; 3) T-shaped terminal phalanges (convergent with other groups); 4) 8 presacral vertebrae; 5) girdle arciferal; 7) palatines present; 8) ventral side and sometimes gastrointestinal organs transparent;
- Distribution limited to Central America through South America, from Venezuela south through Bolivia

## Ceratobatrachidae

107 species in 4 genera

**Commonly Called Ground Frogs**

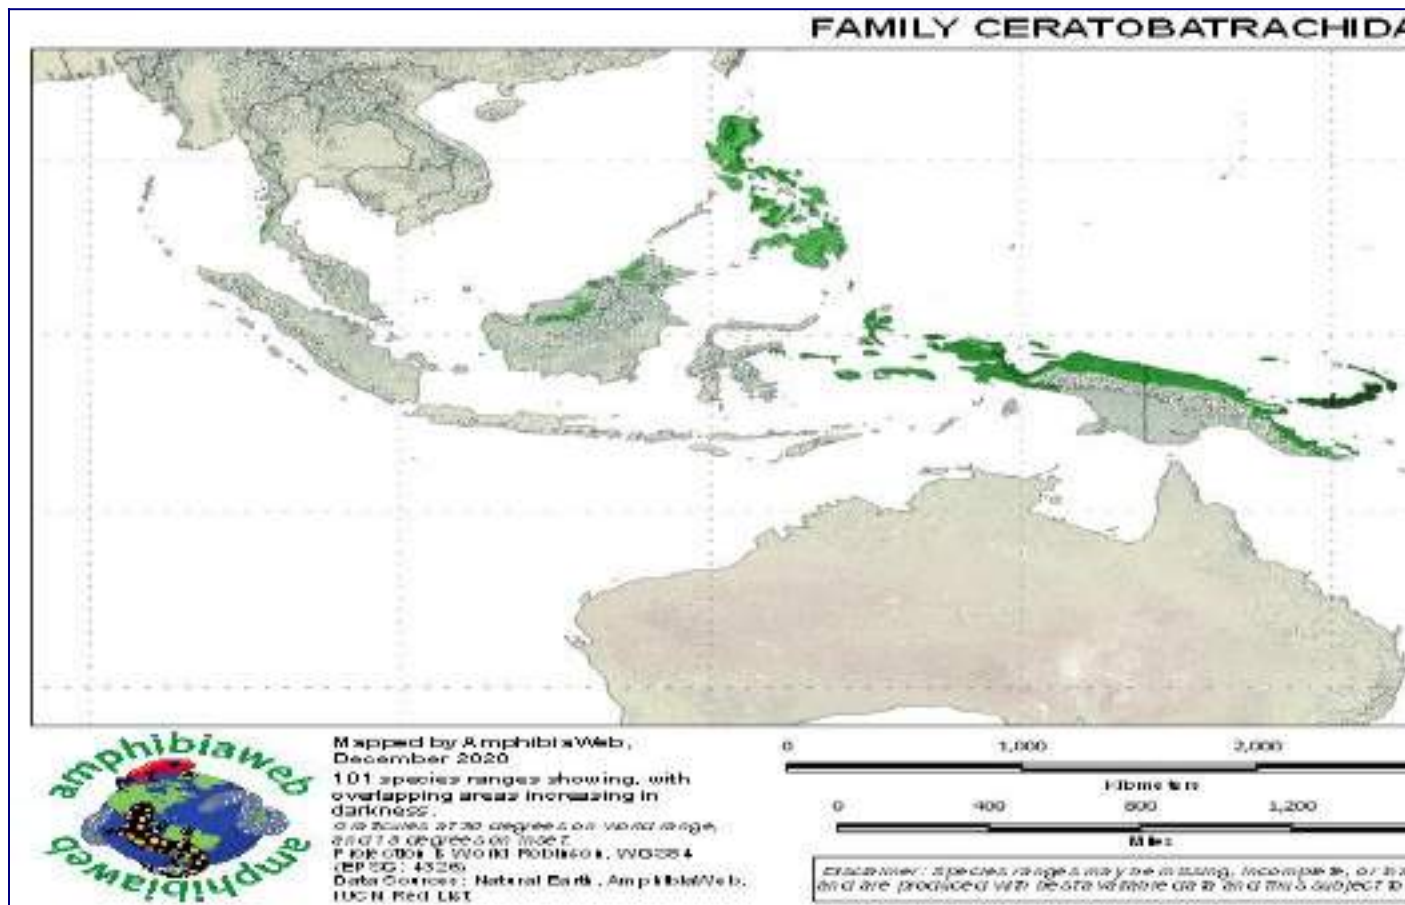

These mostly forest-dwelling frog species are from southeast Asia - Malaysia through the Indonesian islands, archipelago. Much is unknown about the natural history and biology of these species.

Written by AmphibiaWeb

## Notable Family Characteristics

- Direct developers
- Mostly small to medium-sized with some exceptional large species growing up to 165 mm snout-vent
- Terrestrial, with some arboreal species
- Often found in forests, both lowland and montane, or plantations; at least one species is cave-dwelling
- Distribution from Malaysia, Indonesia, Philippines through to east of New Guinea and the Solomon archipelago

## Ceratophryidae

12 species in 3 genera

### *Commonly Called Horned Frogs, Water Frogs*

*Ceratophrys co*  
Photo by Jasper v  
([Click for family](#))

The family Ceratophryidae includes the genus *Ceratophrys*, also known as Horned Frogs, which have huge h gapes. Not all ceratophryids have "horned" appearance but they do have large mouths. These species are sit-a that often mimic dried leaves. In general, they are highly carnivorous with as much as 50% of their prey volum vertebrates (frogs, lizards, snakes, and small rodents).

Formerly part of Leptodactylidae, this group was split out into a smaller family Ceratophryidae that also includ currently in Batrachylidae and Telmatobiidae (they were subfamilies of Ceratophryidae). Subsequent studies o independent groups that were elevated to their present family levels.

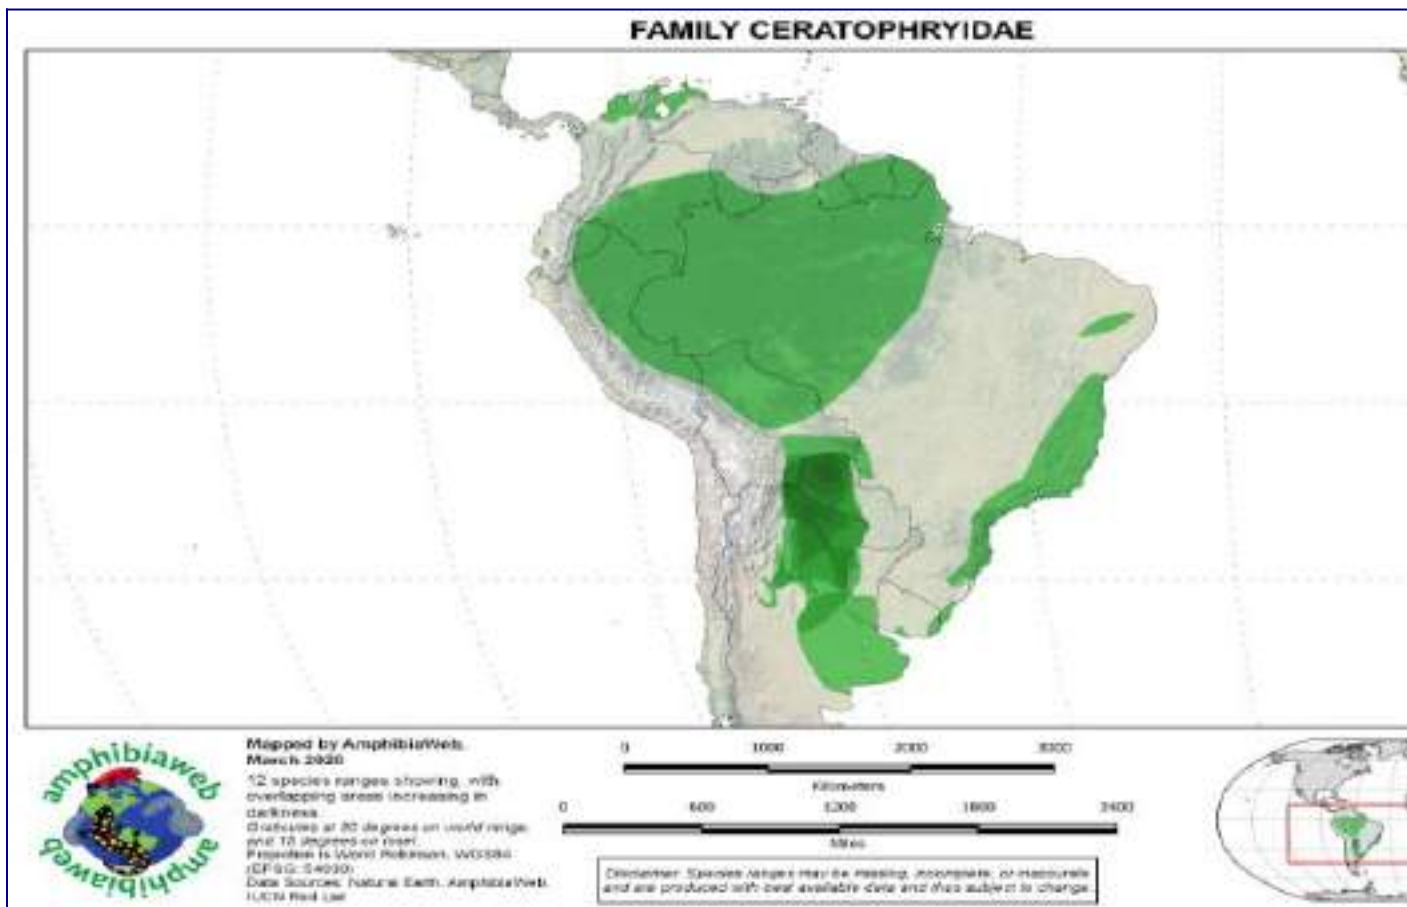

Based on phylogenetic studies (Evans et al. 2008; Ruane et al. 2011), Blackburn and Wake (2011) include thr *Baurubatrachus*, *Beelzebufo*, and *Wawelia*.

Written by AmphibiaWeb

### Notable Family Characteristics

- Fossorial
- Inhabits lowland forests or semiarid regions
- Mostly nocturnal
- Highly carnivorous diet with as much as 50% of their prey volume consisting of vertebrates (frogs, lizards, snakes, and small rodents)

- Large heads and mouths; some species have characteristic 'horns' above each eye
- Distribution limited to South America

## Ceuthomantidae

6 species in 2 genera

***Commonly Called Emerald-Barred Frogs***

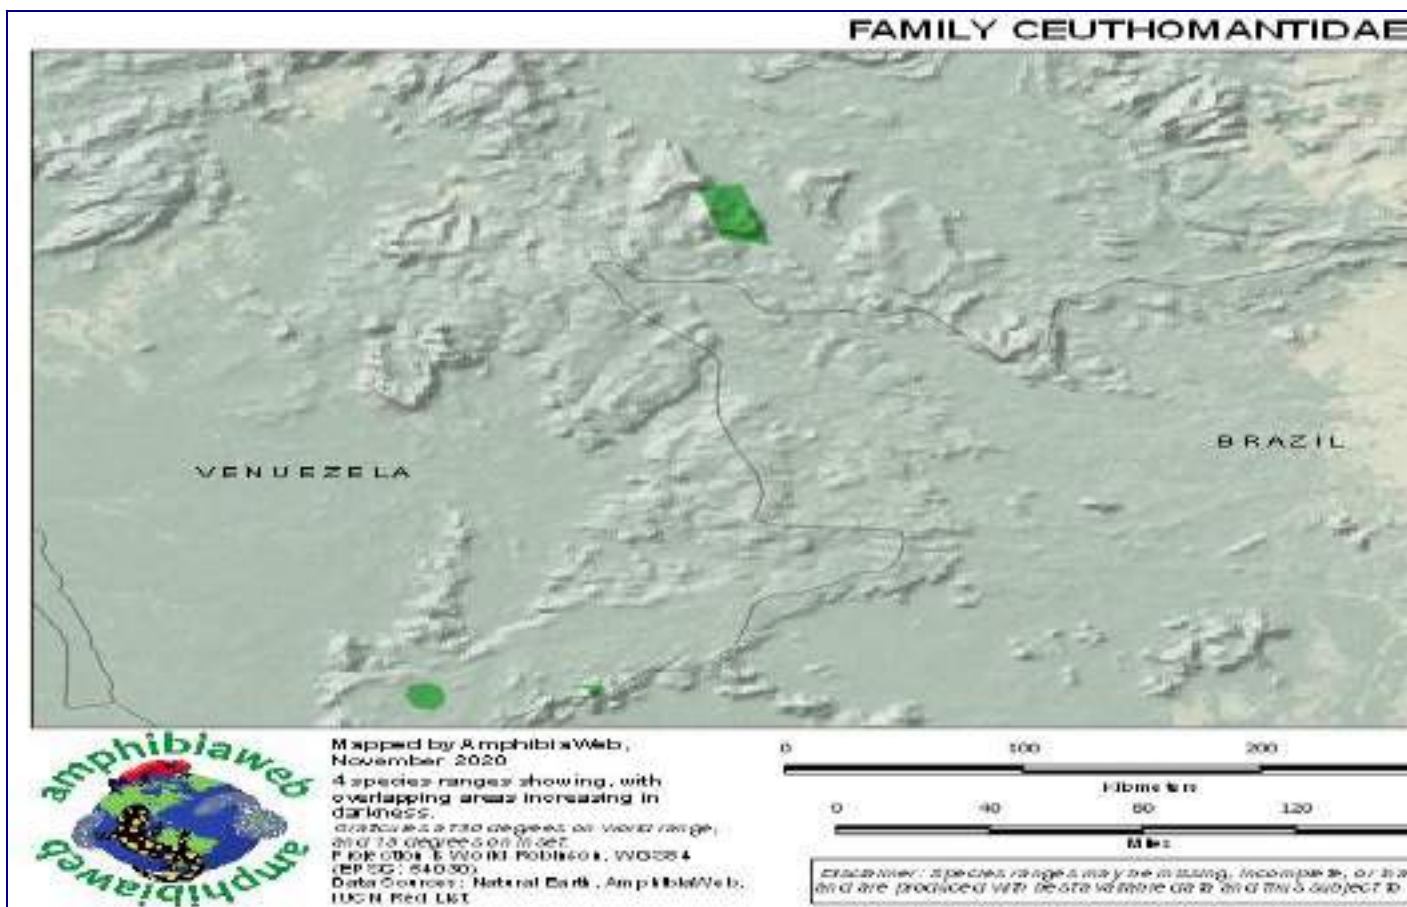

Frogs of the family Ceuthomantidae are found in the elevated mountains and tepuis of the Guiana Shield in northern South America (18-32 mm snout-vent length). Diagnostic characters include: T-shaped terminal phalanges, adductor muscle apophyses, paired lipid-containing protrusions of unknown function in the post-temporal and sacral regions, a very prominent neopalatine bone, notched digital discs on fingers and toes, and the lack of vomerine teeth. The protrusions resemble dorsal

This family is basal within Terrarana (a clade consisting of the families Ceuthomantidae, Brachycephalidae, Cophylinae, and others). The latter four families recognized by Hedges et al. 2008; these families were all originally subsumed within *Eleutherodactylus*. They have direct development of terrestrial eggs, as do other members of the clade Terrarana. Much of their natural history is unknown.

Written by AmphibiaWeb

## Notable Family Characteristics

- Inhabits montane forests and streams above 500 m elevation
- Presumed to have direct development
- Eggs are unpigmented and laid terrestrially
- Diagnostic characters include: T-shaped terminal phalanges, adductor musculature of the "S" type, lack of apophyses on the digit tips, paired lipid-containing protrusions of unknown function in the post-temporal and sacral regions, an ossified neurocranium, an unusually massive neopalatine bone, notched digital discs on fingers and toes, and the lack of vomerine teeth.
- Distribution limited to Guiana Highlands of northeastern South America (Guyana, Venezuela, Brazil)

## Conrauidae

8 species in 1 genus

***Commonly Called Goliath Frogs, Slippery Frogs***

*Conraua robusta*  
Photo by Brian Freiermuth

[\(Click for family gallery\)](#)

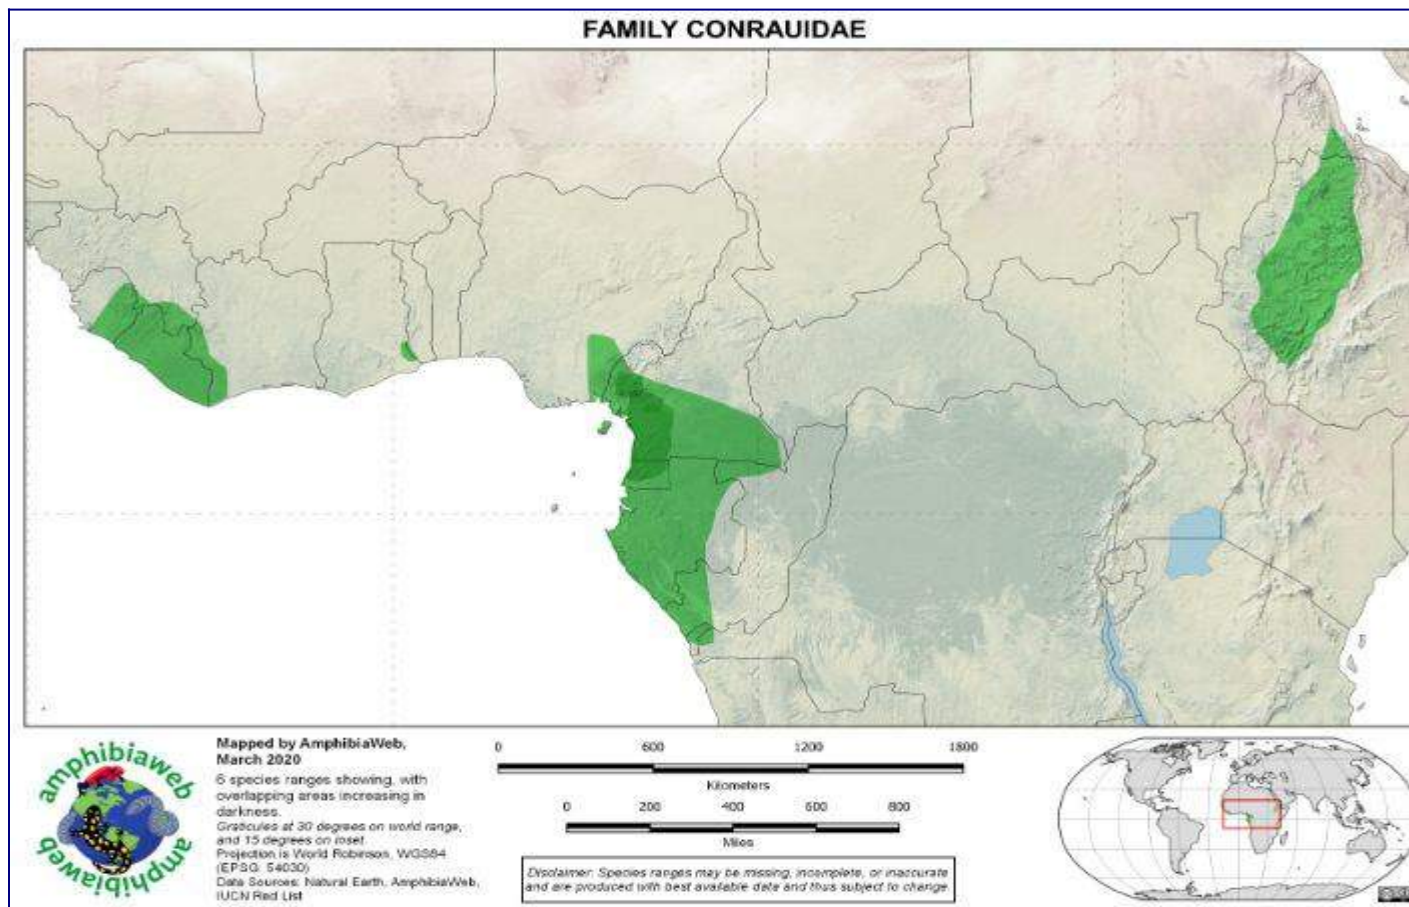

Much of the information on this family comes from the most famous member, the Goliath frog (*Conraua goliath*), which is the largest known species of frog. Individuals may weigh up to 4 kilograms (8 lbs) and up to 32 cm snout-vent length. These species are poorly known and many are consumed for food.

The closest sister group to Conrauidae is likely Petropedetidae (both were formerly subfamilies to Ranidae) as summarized by Blackburn and Wake (2011).

Written by AmphibiaWeb

## Notable Family Characteristics

- Found in riverine systems and tannic, clear waters
- Lays eggs in moving water
- Lack vocal cords, at least in *Conraua goliath*
- Distribution is disjunct in West Africa and in East Africa

## Craugastoridae

136 species in 3 genera

***Commonly Called* Fleshbelly Frogs, Brittle-Belly Frogs, Robber Frogs**

The family Craugastoridae consists of direct developing frogs, with a disjunct distribution; the genus *Craugastor* is found in northern South America and Central America and into northwestern South America, while the genus *Haddadus* is found in southeastern South America. The family is thought to have originated about 59 million years ago, before the major Andean uplift. The organization of the family has a complicated history, with some members being placed in Eleutherodactylidae, Ceuthomantinae or Holoadeninae with conflicting evidence for the superfamily of Brachycephaloidea or Strabomantidae.

Members of this family range in size from 18 mm snout-vent length in female *Craugastor pygmaeus* to 110 mm in male *Haddadus*.

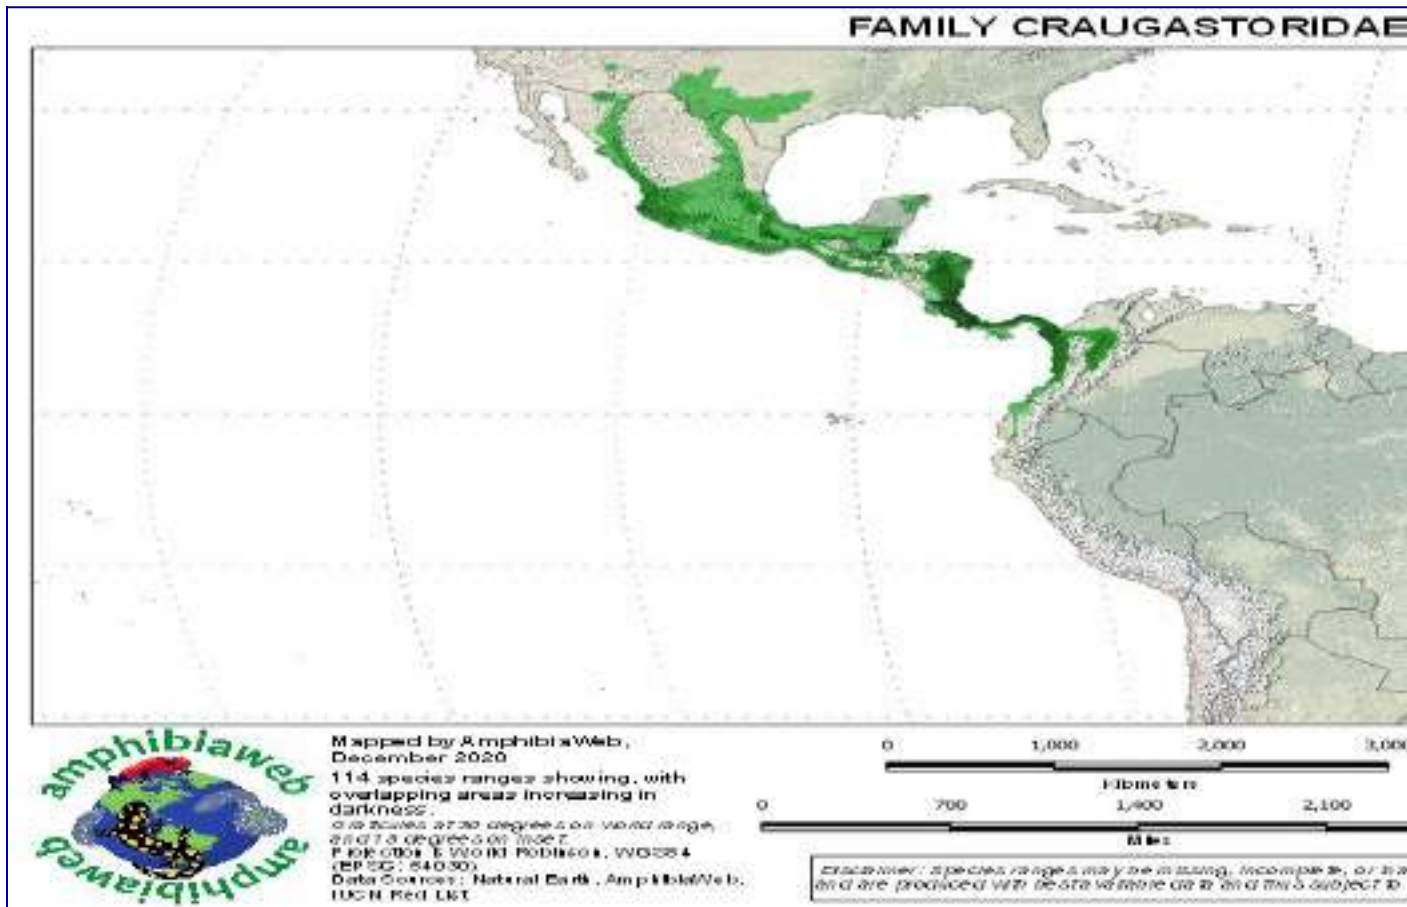

litter of forest floors although some species occurs in more rocky outcrops (*Craugastor augusti*).

Several species of this group are believed extinct: *Craugastor chrysozetetes* from Honduras and *Craugastor e...* in the wild for decades despite extensive field efforts.

Written by AmphibiaWeb

## Notable Family Characteristics

- Terrestrial, occurring in the leaf litter or along streams in forests, with one species known from rocky outcrops (*Craugastor augusti*)
- Axillary amplexus
- Direct development, with eggs deposited terrestrially or arboreally
- Many species with some form of parental care (Savage 2002)
- Morphological characters include: 1) Finger I longer than Finger II, in most species; 2) unwebbed fingers; 3) prominent external glands on the body; 4) digit tips expanded into pads having circummarginal grooves; 5) outer metatarsal tubercles present; 6) tympanic membrane and annulus usually distinct (Hedges et al. 2008)
- Osteological characters include: 1) cartilaginous sternum; 2) vertebral shield not present; 3) transverse processes of posterior presacral vertebrae not broadly expanded; 4) widely spaced cervical cotyles; 5) eight presacral vertebrae; 6) Presacrals I and II not fused; 7) omosternum present; 8) sacral diapophyses rounded or barely dilated; 9) maxillary teeth usually dentate, with blunt, pedicellate teeth; 10) alary processes of premaxillae are broad at base, usually directed dorsally or posterodorsally; 11) palatal shelf of premaxilla usually broad, indented or not; 12) pars facialis usually deep, not exostosed; 13) palatal shelf of maxilla moderately broad, may bear pterygoid process; 14) maxillary arch complete; maxillae taper posteriorly; quadratojugal slender; 15) nasals usually in contact; not usually in contact with maxillae or pterygoids; not in contact with frontoparietals; 16) frontoparietals usually absent; 17) fontanelle usually absent; 18) frontoparietals usually not exostosed; cranial crests present or not; 19) carotid artery passing dorsal to cranial elements; 20) zygomatic ramus of squamosal broad to slender, usually in contact with maxilla; 21) squamosal-maxilla angle 44-67°; 22) columella present; fenestra ovalis directed laterally; 23) broad neopalatines; 24) sphenethmoid entire; 25) anterior ramus of parasphenoid not keeled; 26) parasphenoid at right angle to axis of skull or deflected posteriorly, usually not overlapped by pterygoids; 27) pterygoid flange; 28) occipital condyles widely separated medially; 29) odontoids lacking; 30) T-shaped terminal phalanx in three phalanges in Finger IV; 31) Toe I fully developed and free; 32) mandibular ramus of trigeminal nerve passing lateral to the m. adductor mandibulae ("S" condition) in *Haddadus*, passing medially ("E" condition) in *Craugastor* (Hedges et al. 2008).
- Distribution limited to southwestern United States through Mexico and Central America and into northern South America (*Craugastor*) as well as southeastern Brazil (*Haddadus*)

## Cycloramphidae

38 species in 3 genera

***Commonly Called Button Frogs. River Frogs, or Bug-Eyed Frogs***

The family Cycloramphidae contains genera formerly considered to be within the family Leptodactylidae, and *Rhinoderma*, Mouth-Brooding Frogs, now considered as a separate family, the Rhinodermatidae. Cycloramphids inhabit terrestrial or semi-terrestrial habitats of primary or secondary forests, streams and rocky outcrops in South America. Some live in fast-moving torrents of mountain streams; others are considered semi-terrestrial living in the rocks in the streambanks (*Cycloramphus*). The placement of the genus *Zachaenus* was once considered too uncertain for firm placement.

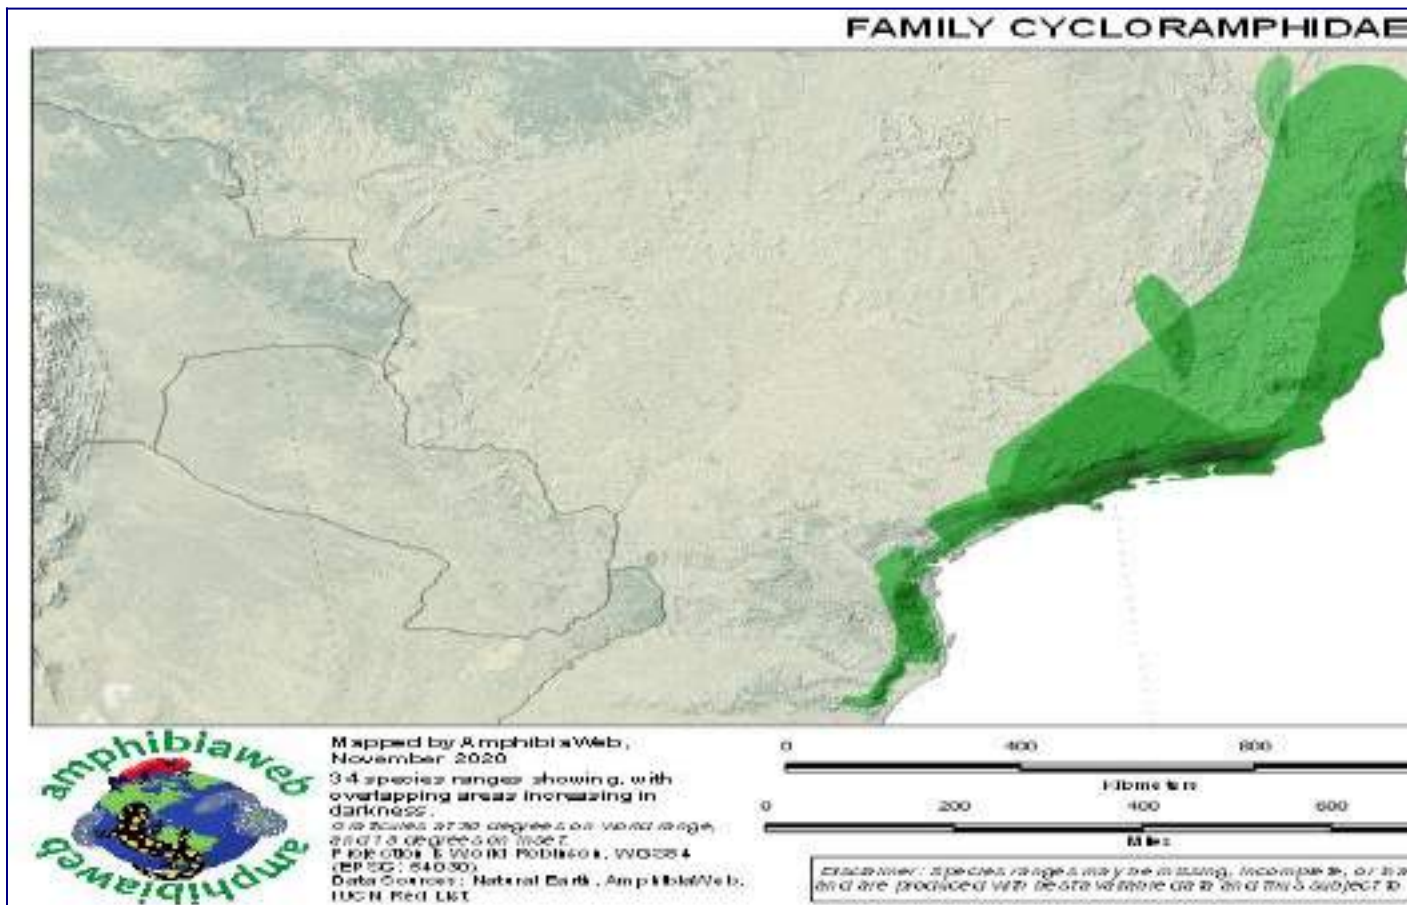

**News Highlight:**

November 25, 2019: In frogs, breeding in water is the ancestral condition. Yet terrestrial breeding has evolved in the Neotropical frog genera *Cycloramphus* and *Zachaenus* (family Cycloramphidae). Terrestrial breeding is thought to have evolved as a way to escape threats to eggs and larvae from aquatic predators. Terrestrial breeding could be the high costs associated with high male-male competition and guarding of limited nest sites in rocky streams, which leads to high competition among males for high-quality nest sites. Increased male-male competition leads to selection for larger males, reducing the size differences between males. The abundance of sites on land to create nests dramatically lowers the degree of male-male competition and smaller body sizes are particularly important on land where desiccation risk is high and being smaller reduces size dimorphism becomes enhanced as selection for larger males is reduced, allowing males to evolve smaller sizes. Larger males are larger to be able to better produce eggs. They nicely illustrate how natural and sexual selection in conjunction influence the diversification of amphibian life. (MLambert)

Written by AmphibiaWeb

### Notable Family Characteristics

- Terrestrial or semi-terrestrial habitats of primary or secondary forests, streams and rocky outcrops
- Amplexus axillary
- Eggs are laid and hatch into free-living tadpoles with adaptations to semi-terrestrial or torrential stream habitats
- Some morphological features include: 1) paired palatines and frontoparietals in the skull; 2) eight presacral vertebrae, all procoelous
- Distribution limited to southeastern Brazil in the Brazilian Atlantic rainforest of South America

## Dendrobatidae

214 species in 16 genera

**Commonly Called Poison-arrow Frogs, Dart-poison Frogs, Poison-dart Frogs**

Species of this family are small, brightly colored, neotropical frogs. Dart-poison frogs derive their name from skin alkaloids, obtained through the insects they eat. Three species (*Phyllobates terribilis*, *Phyllobates aurota*) poisoning blow-gun darts for hunting animals in Colombia. The most toxic species of any frog is *Phyllobates* at a level approximately 20-fold that of other dart-poison frogs.

Dendrobatids have short but strong hind limbs and are agile jumpers and climbers. They are characterized by

surface of their digits. These frogs are diurnal and lay eggs on land. Many dendrobatid species exhibit parental care, including transporting their tadpoles on the back of the parent. In some species, each tadpole is placed in a separate tree. Both parents visit the tadpoles periodically, with the female depositing unfertilized eggs at each visit to feed them. Males and females also engage in and wrestling competitions and display cephalic amplexus (grasping the female around the head during mating).

This family has had several taxonomic revisions and examinations (e.g., Grant et al., 2006; Santos et al., 2010; Grant et al., 2010 summary). Species from three former subfamilies (Allobatinae, Anomaloglossinae, and Aromobatinae) now fall within this family.

### News Highlight

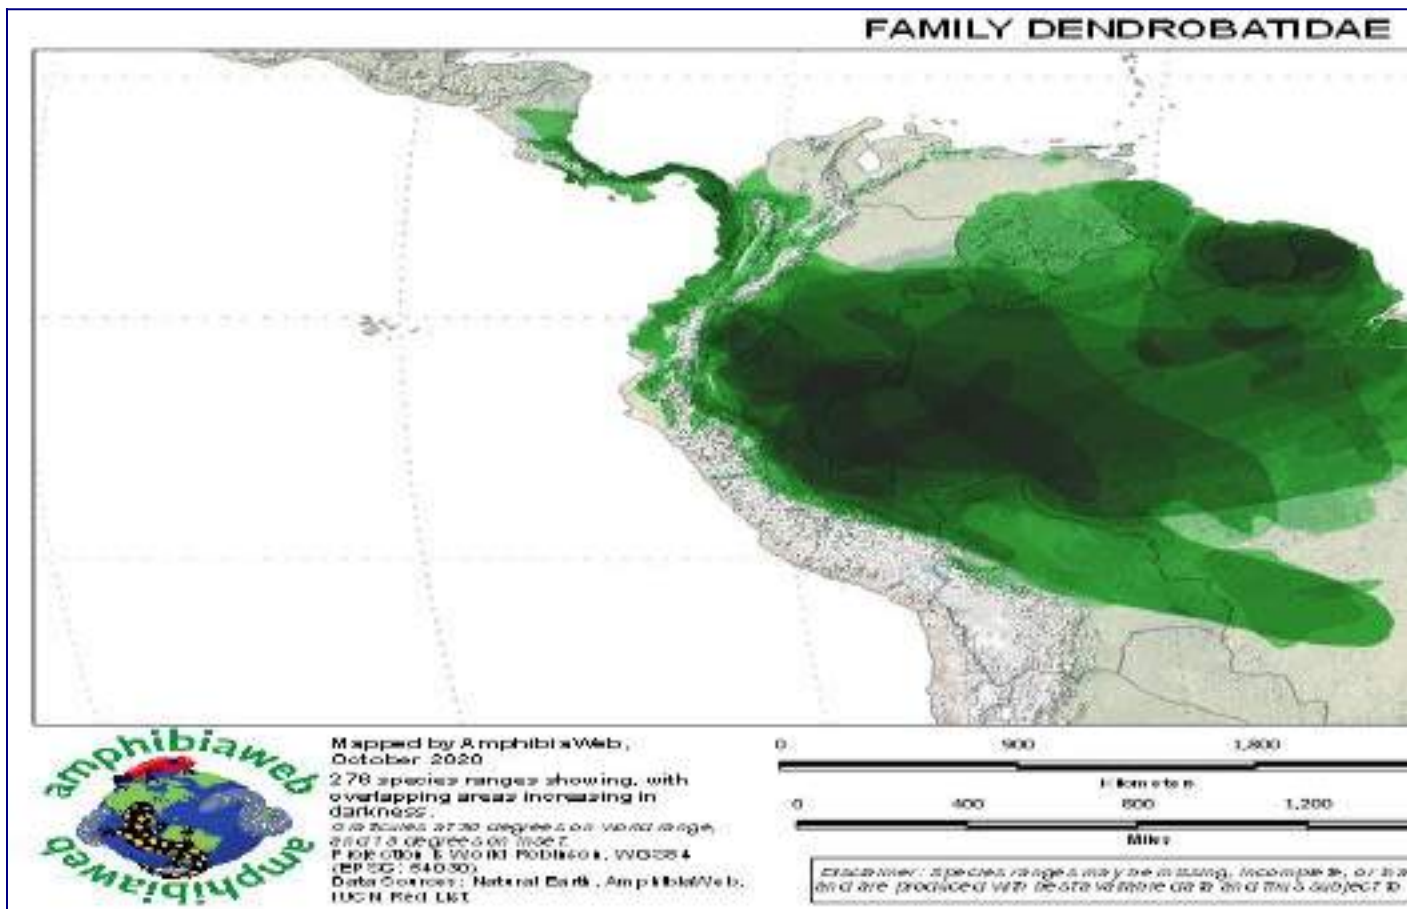

October 30, 2017: Although many animals avoid toxic prey, some use the toxins of their prey to ward off predators. However, unless they can resist their own toxins. [Tarvin et al. \(2017\)](#) found that in poison frogs the basis of self-resistance is a change that evolved in three groups; nature hit upon the same solution repeatedly. This change occurs in the epibatidine receptor. Epibatidine makes the receptor more resistant to epibatidine, but it inhibits normal function by decreasing acetylcholine release. In some poison frogs evolved additional mutations that compensate for the cost by making the receptor more normal, but the negative effect of epibatidine is still reduced. (DCC)

May 8, 2017: Many amphibian species that are phenotypically indistinguishable are genetically very distinct. In the reverse case, in which interspecific variation in traits such as color is high, relative to genetic divergence, a study of a poison frog group *Epipedobates*, found that among species that are otherwise easily distinguishable by color. Moreover, this rapid divergence resulted in two independent origins of colorful aposematic species. Producing a distinct aposematic phenotype.

Written by AmphibiaWeb

### Notable Family Characteristics

- Diurnal
- Cephalic amplexus (unique among frogs)
- Eggs are laid, hatch into tadpoles and cared for by parents
- Males may be highly territorial and 'combat' each other
- Morphological characters include: 1) thickened pads or scutes on dorsal surface of digits; 2) toxic skin
- Distribution limited to the neotropical rainforests of Central and South America

## Dicroglossidae

265 species in 15 genera

### Commonly Called Forked-Tongue Frogs, Cricket Frogs

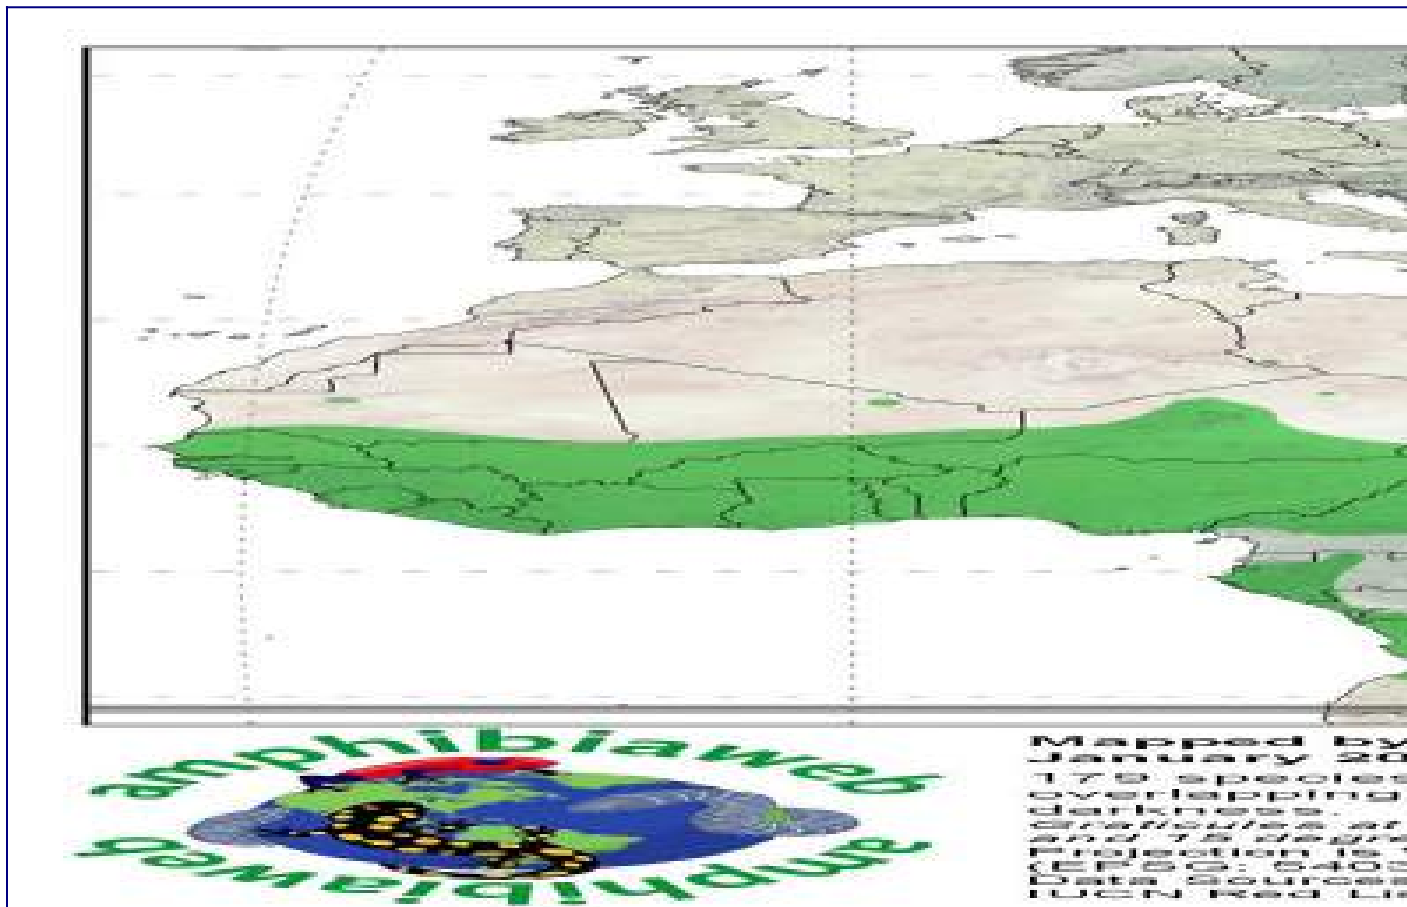

This large family has a diversity of forms and natural history modes; likewise it has had a sometimes confusing history. More species are yet to be described in this family.

They range from sub-Saharan Africa south to South Africa east through western Asia, South Asia (India), China, and Southeast Asia.

Written by AmphibiaWeb

### Notable Family Characteristics

- Terrestrial and aquatic species, found in a diversity of habitats
- Both egg-laying and direct developing species
- Diverse reproductive modes including uncommon inguinal amplexus in *Occidozyga sumatrana*
- Includes crab-eating frog *Fejervarya cancrivora* with unique specializations for living in brackish marshes
- Includes burrowing species like *Sphaerotheca breviceps*, which appear above ground after heavy rains
- Distributed through sub-Saharan Africa, western Asia, South Asia (India), Southeast Asia, Philippines, and Indonesia

## Eleutherodactylidae

241 species in 4 genera

### *Commonly Called* New World Rain Frogs

This family is an assemblage of four genera of direct-developing frogs found throughout the West Indies, in p and from southern Texas (USA) south to northwestern Ecuador, with some genera in northeastern South Ame. Eleutherodactylidae range in size from 10.5 mm snout-vent length in female *Eleutherodactylus iberia* to 88 m. *Eleutherodactylus iberia* is one of the smallest frogs in the world. Miniaturization has occurred across five far Leptodactylidae, Microhylidae, and Sooglossidae), and with it come constraints in morphological developmen. Miniaturized frog species also tend to have high-frequency calls (>5 kHz) and to have clutches with very sma

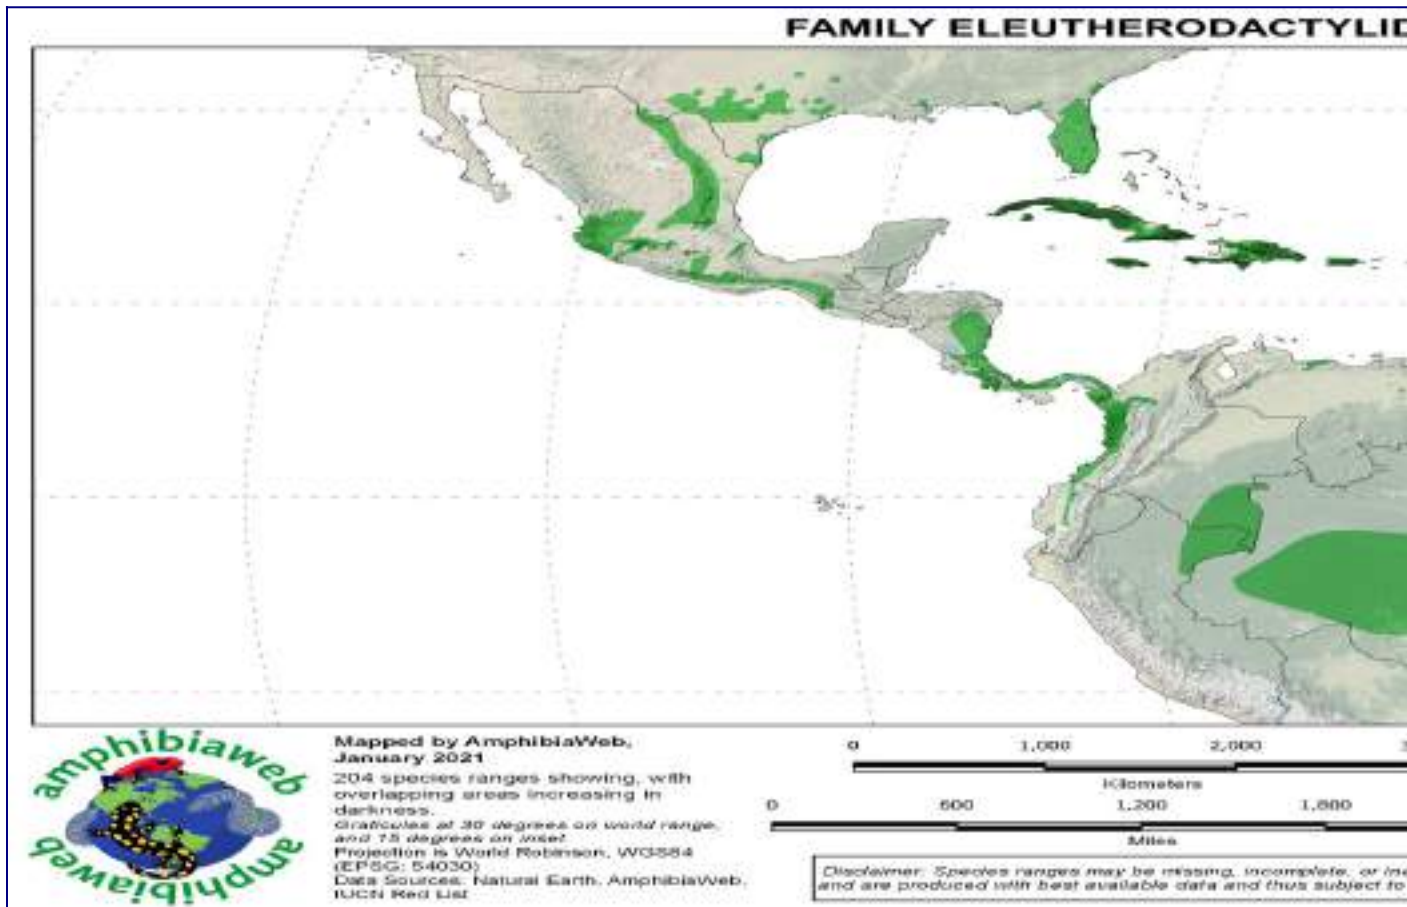

An unusual species is *Eleutherodactylus jasperi*, the only ovoviviparous eleutherodactylid, which retains deve froglets. This species is endemic to southern Puerto Rico, but is thought to be extinct as it has not been seen s

Written by AmphibiaWeb

### Notable Family Characteristics

- Inhabits forests and heavy vegetation
- Internal fertilization in at least a few species (*Eleutherodactylus coqui*, *E. jasperi*)
- Eggs are deposited terrestrially or arboreally and undergo direct development; ovoviviparity exists in a

- Amplexus axillary
- Species in this family share the following characters: (1) cartilaginous sternum; (2) vertebral shield not expanded broadly; (4) cervical cotyles widely spaced; (5) eight presacral vertebrae, with Presacralis overlying skin; (7) omosternum present; (8) sacral diapophyses rounded to barely dilated; (9) maxillary processes of premaxillae broadened at base, usually directed dorsally or posterodorsally; (11) palatal shelf of maxilla usually deep, not exostosed; (13) palatal shelf of maxilla moderately broad, may be broadened posteriorly; (14) maxillae tapering posteriorly; quadratojugal slender; (15) nasals usually large with broad median contact; (17) nasals not in contact with frontoparietals; (18) frontoparietal fontanelle usually absent; (19) frontoparietals fused with prootics or not; (20) frontoparietals fused with prootics or not; (21) temporal arcade absent; (22) epitympanic process of malleus dorsal to cranial elements; (24) zygomatic ramus of squamosal broad to slender, usually not in contact with zygomatic process of maxilla; (25) squamosal may be expanded into otic plate or not; (26) squamosal-maxilla angle 44 - 67°; (27) columella present, except in *Eleutherodactylus* (subgenus *Syrrhophus*), and some diminutive species; dentigerous processes absent in *Eleutherodactylus* (subgenus *Syrrhophus*), and some diminutive species; (28) sphenethmoid usually broad; slender in *Eleutherodactylus* (subgenus *Syrrhophus*); (30) sphenethmoid usually entire, anterior ramus of parasphenoid narrow to broad, no keel; (32) parasphenoid alae either present at right angles to parasphenoid or not; (33) pterygoid lacks ventral flange; anterior ramus does not reach neopalatine medially, may be stalked or not; (35) odontoids lacking; (36) terminal phalanges T-shaped; (37) usually present; (38) Toe I fully developed and free; (39) alary process of hyoid plate may be on slender stalk or not; (40) mandible with adductor mandibulae (condition unknown in *Adelophryne*); (41) prominent external body glands usual in *Eleutherodactylus*; (42) males have single or paired subgular vocal sac, single pectoral vocal sac, or none; (43) hands with pads; (44) hands unwebbed; feet usually unwebbed or webbed basally, but foot webbing is extensive in some species with pads set off by distinct circumferential grooves; digits apically pointed in *Adelophryne* and some species; (45) inner and outer metatarsal tubercles present, inner tubercle not spade-like; (47) tympanic membrane absent
- Distribution through the Caribbean, including Florida and southern Texas in the United States, Central

## Heleophrynidae

6 species in 2 genera

### *Commonly Called Ghost Frogs*

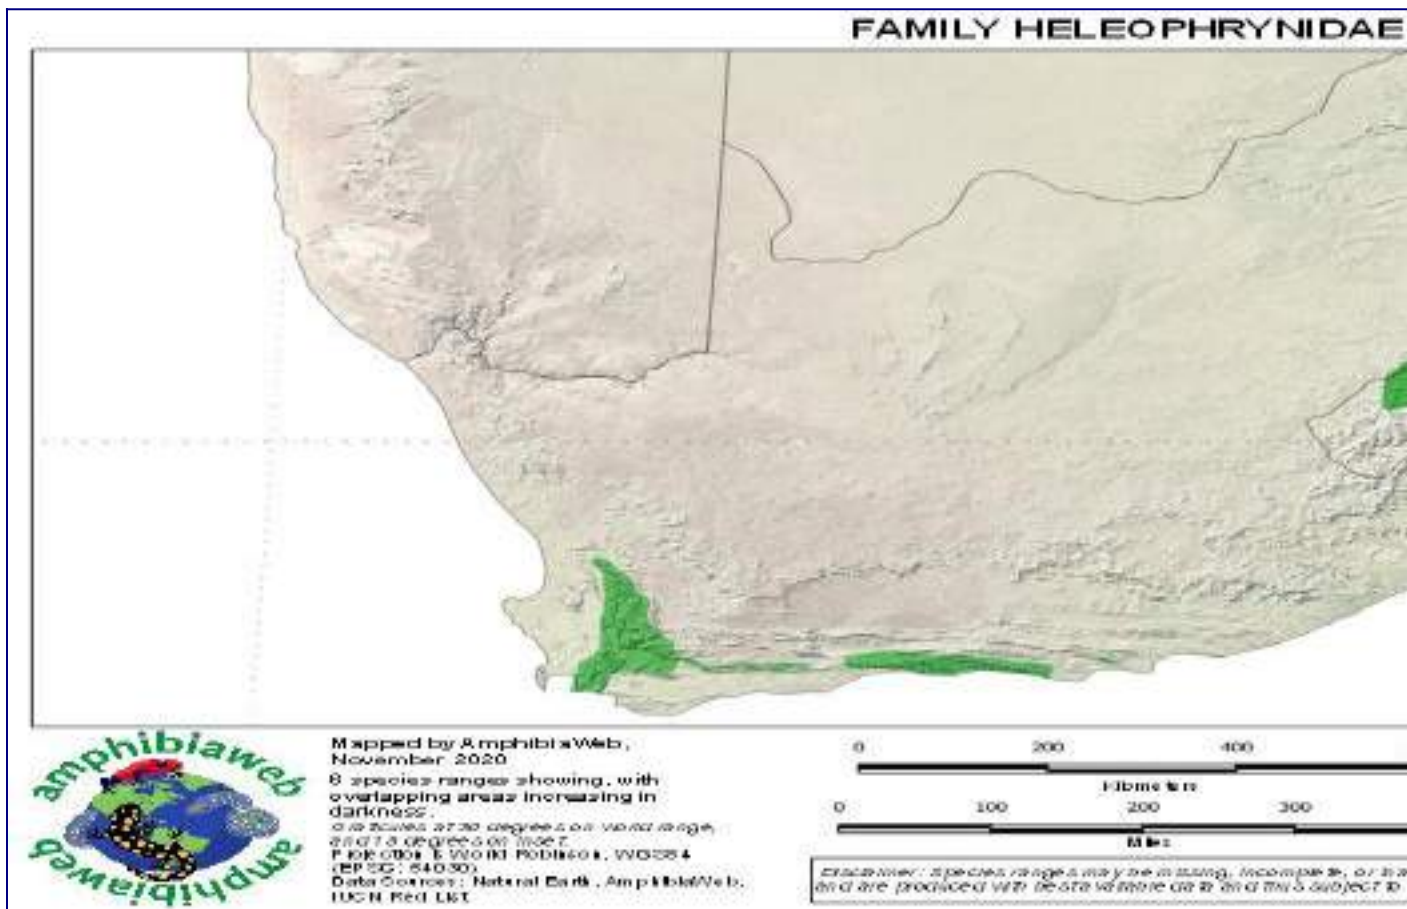

This small family of slender, agile frogs is restricted to the southern tip of Africa, where its members are found. *Heleophryne* and *Hadromophryne*, comprise this group. Adults have large eyes, vertical pupils, and triangular toe discs. They have a brown or green background. Due to their cold habitat, tadpoles are slow to develop. Major morphological characters include the presence of many rows of denticles, as well as the presence in adults of triangular toe discs. Members of this family become more aquatic during breeding season.

Heleophrynidae is the sister taxon of all remaining Neobatrachia, which is majority of all frogs.

Written by AmphibiaWeb

### Notable Family Characteristics

- Inhabits high elevation montane forests and cold, fast-moving streams
- Tadpoles are Type 4 (Orton) and have large suction oral discs with many denticles but no keratinous bands
- Morphological characters include: large eyes, vertical pupils, webbed frogs, triangular toe discs
- Distribution limited to the mountainous regions of southern Africa

# Hemiphractidae

127 species in 6 genera

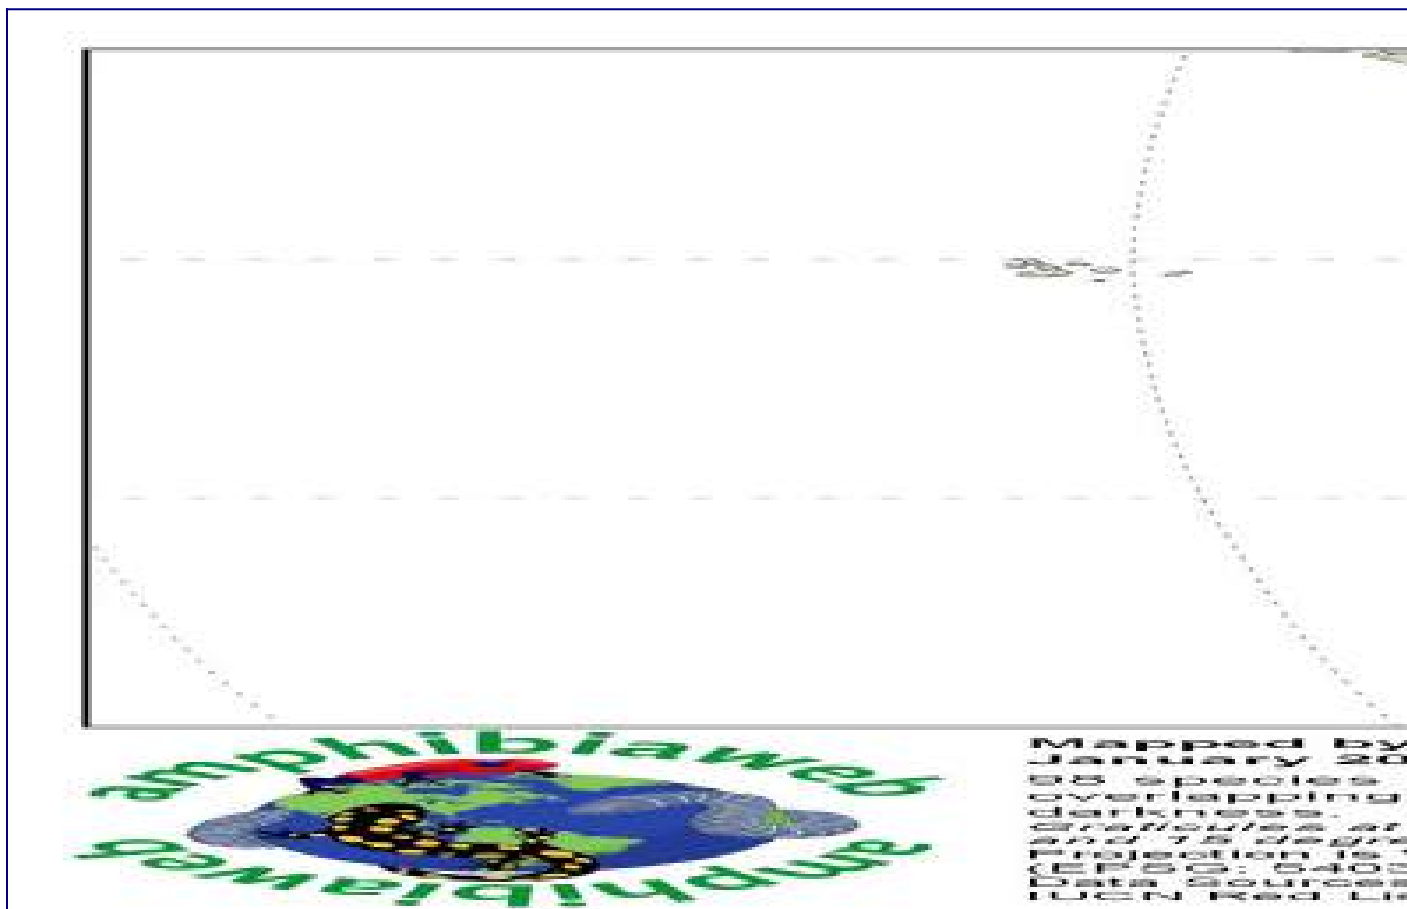

***Commonly Called Horned Frogs, Marsupial Frogs***

The family Hemiphractidae is known for its direct-development with a unique means of parental care. These *pygmaeus* have embryos with two pairs of bell-shaped gills, which derive from the first and second branchial

Written by AmphibiaWeb

## Notable Family Characteristics

- Terrestrial
- Tropical rainforests
- Direct development; specialized dorsal pouch houses the eggs until they hatch as froglets (*Flectonotus*)
- *Hemiphractus* have distinct triangle-shaped heads and spiky protuberences above their eyes, on their r
- Distribution in South and Central America, in Brazil, Colombia, Ecuador, Peru, and Panama.

## Hemisotidae

9 species in 1 genus

***Commonly Called Shovel-nosed Frogs, Pig-nosed Frogs***

*Hemisus marmoratus*

Photo by Robert C. Drew

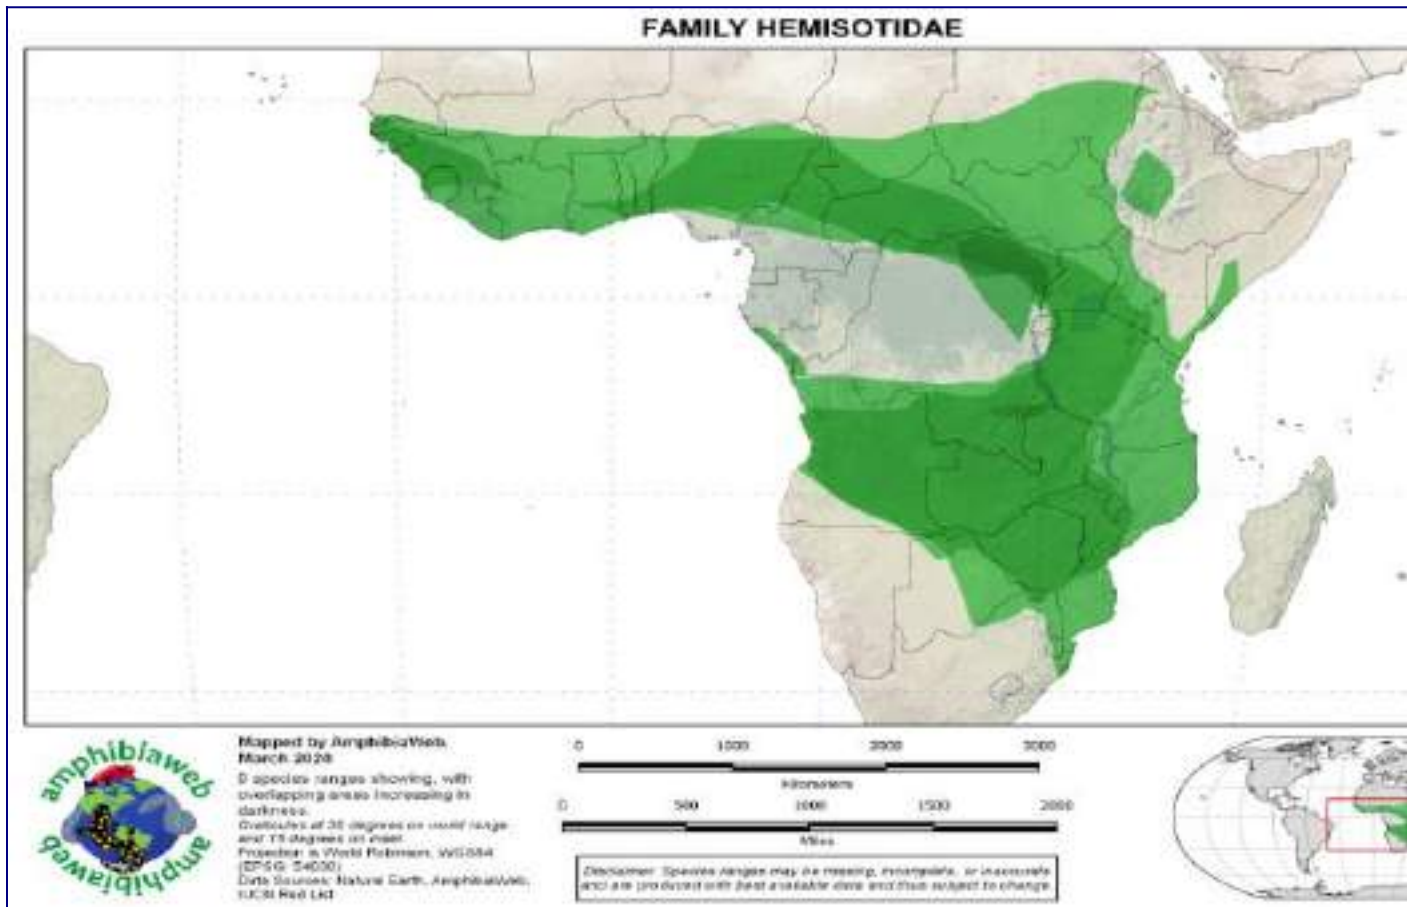

[\(Click for family gallery\)](#)

The family Hemisotidae is made up of shovel-nosed, globose-bodied frogs within a single genus, *Hemisus*. Their pointed snouts, strong forelimbs and hindlimbs, and loss of a sternum (convergent in *Rhinophrynus*) allow them to be quick and efficient headfirst burrowers in tropical savanna of sub-Saharan Africa. They lay eggs underground near the end of the dry season. Nests are flooded and tadpoles then swim to temporary pools of water to finish their development. Tadpoles also wriggle onto the parent's backs to be transported to water.

Written by AmphibiaWeb

### Notable Family Characteristics

- Inhabits tropical savannah, open plains
- Inguinal amplexus
- Parental care in the form of transporting tadpoles to pools after hatching
- Morphological features include: 1) hard-pointed snouts; 2) strong forelimbs and hindlimbs; 3) absence of sternum; 4) hardened skulls, which allow for head-first burrowing
- Distribution limited to sub-Saharan Africa

## Hylidae

1085 species in 85 genera

### *Commonly Called Treefrogs, Leaf Frogs*

These are the Treefrogs, a wide-spread family especially well represented in the New World. Hylids range from discs that contain a cartilage offsetting the terminal phalanx (the intercalary cartilage), which may aid in climbing. This family is one of the largest families of anurans with over 900 species recognized. This family was taxonomically revised and the subfamilies are:

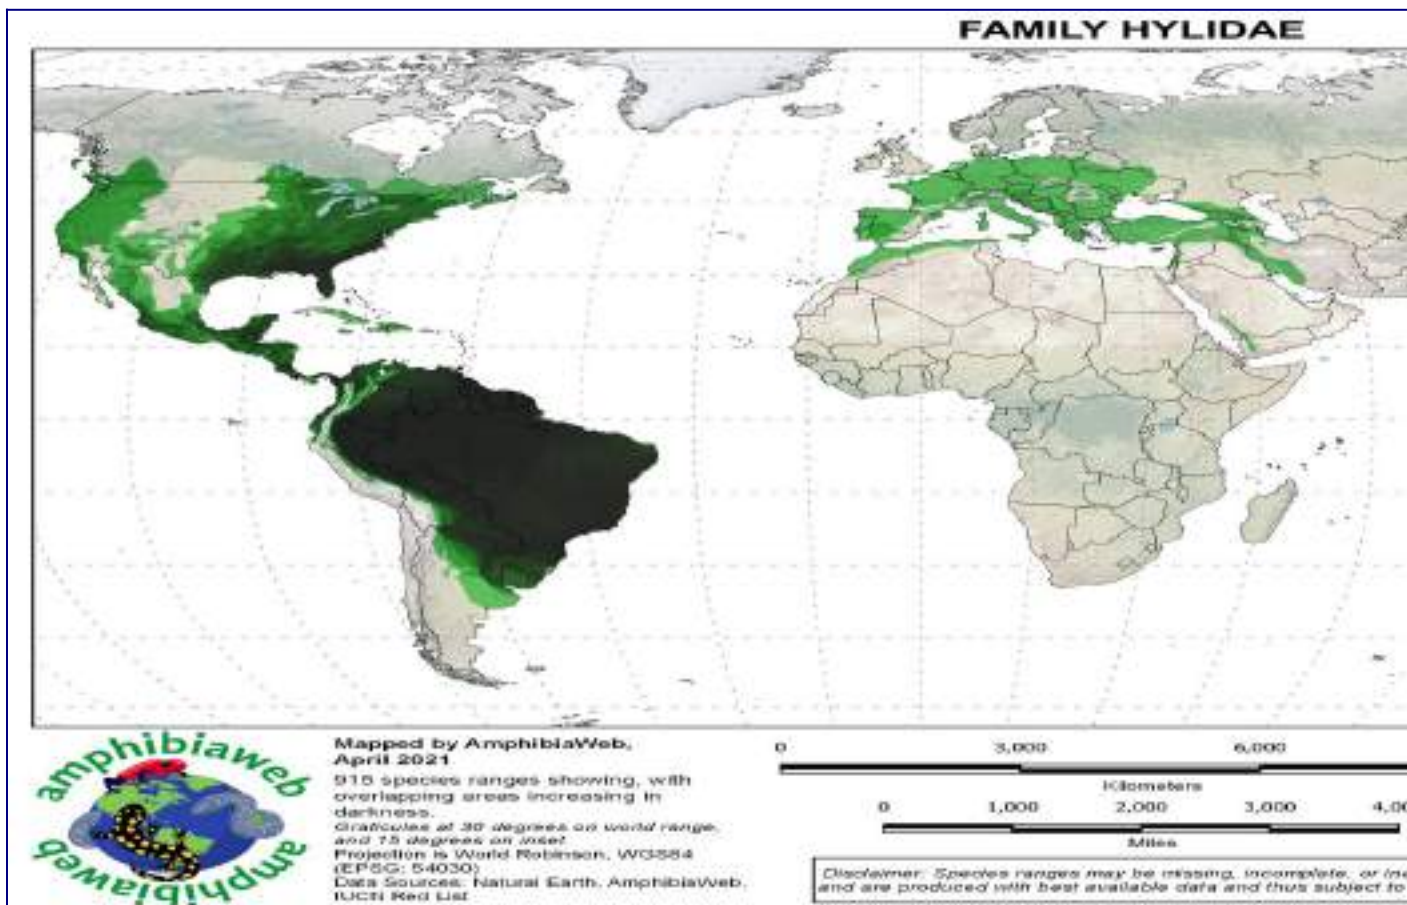

1. **Hylinae** (Treefrogs of North, Central, and South America, Eurasia and North Africa). This subfamily is the largest and most diverse. This subfamily by Faivovich et al. (2005) recognized four tribes and 45 genera, many newly named. One of the members of this large clade have claw-shaped terminal phalanges (also convergent with some Hyperoliids). One of the members is *Pseudis paradoxa*, whose tadpoles reach an enormous size of up to 220 mm but subsequently metamorphose into small adults.
2. **Pelodryadinae** (Australian/Papua New Guinean treefrogs). Contains the curious *Cyclorana platycephala*, which can stay underwater for long periods. Indigenous Australians and squeezed for the water in its bladder. Represented by over 200 species in 3 genera.
3. **Phyllomedusinae** (Central and South American arboreal leaf frogs). Comprised of 7 genera (*Agalychnis*, *Phyllomedusa*, and *Phyllomedusa*) distributed from Mexico through Central and South America. They are mostly arboreal and live in water, but some breed in tree/log cavities. One famous member of this group is the Waxy-Monkey Tree Frog, which secretes a waxy substance and avoids desiccation by wiping lipid secretions over its body. Another well-known species is the bright green tree frog, which attaches its egg clutches to leaf surfaces overhanging water. Embryos develop within the eggs and fall out when the eggs are ready. Whether different vibration patterns portend immediate predation by wasps or snakes or are simply due to environmental factors is a matter of decisions whether to hatch early (to avoid being eaten by wasps or snakes, but risk being eaten by aquatic predators).

rainfall), since older embryos have better ability to evade aquatic predators when they do hatch and fall

Written by AmphibiaWeb

## Notable Family Characteristics

- A wide range of habitats, from tropical and temperate forests to deserts and montane ecosystems
- Most species are arboreal although some are more terrestrial, aquatic or even semi-fossorial
- A range of reproductive modes, all with aquatic tadpoles from eggs laid in ponds, on leaves or in bromeliad  
marches, or treeholes
- Axillary amplexus
- Morphological characteristics include: 1) skull with paired palatines and frontoparietals; 2) eight presacral  
vertebrae; 3) pectoral girdle is arciferous with a well-defined sternum; 4) fibulare and tibiale are at both ends of the  
present between terminal and penultimate phalanges; 6) toepads may be pointed in terrestrial species and  
species; 7) horizontal pupils
- Distribution worldwide, with many species in the North, Central, and South America as well as Eurasia

## Hylodidae

49 species in 4 genera

## ***Commonly Called Torrent Frogs, Stream-dwelling Frogs***

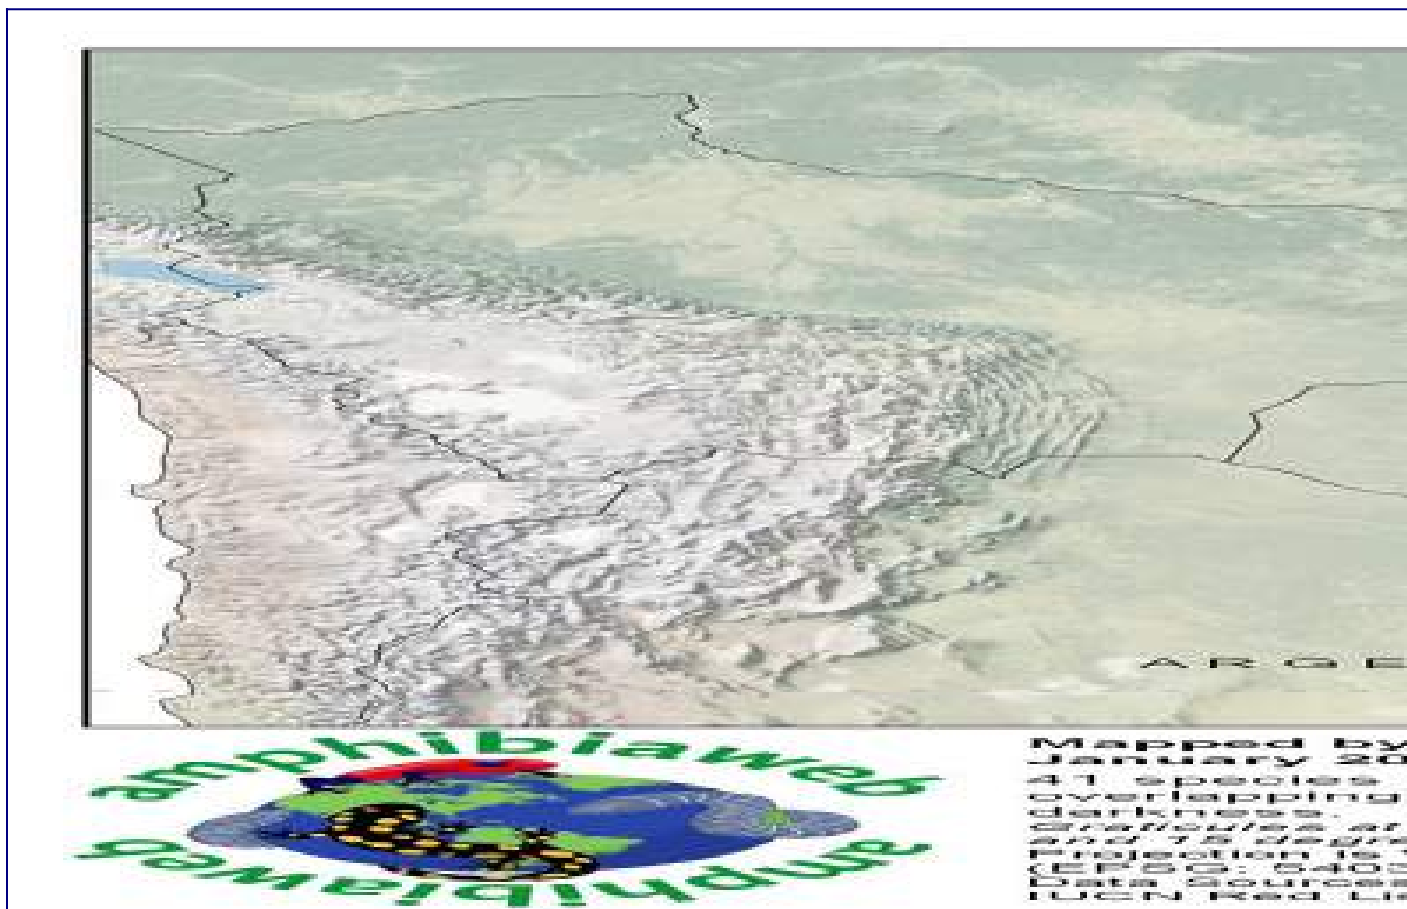

The family Hylodidae occurs in northwestern Brazil to southern Brazil and northern Argentina. One unusual member is the

This family is sister taxon to Alsodidae.

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Occurs in and around streams, some species preferring fast-moving waters and waterfalls
- Diurnal
- Axillary amplexus
- Egg-laying in water with aquatic tadpoles
- Morphological characters include: 1) cartilaginous sternum (although may be calcified in older adults), 2) vocal sacs in some species of males
- Distribution limited to South America, northwestern and southern Brazil to northern Argentina

## Hyperoliidae

236 species in 17 genera

***Commonly Called African Reed Frogs, Running Frogs***

The family Hyperoliidae consists of over 200 species. The diversity of hyperoliids is restricted to sub-Saharan Africa. Many species exhibit bright colors and striking patterns, which are sexually dimorphic in some species. One e

Taxonomy is still unsettled for some groups within Hyperoliidae, particularly the following:

The *Hyperolius nasutus* group, consisting of *H. nasutus*, *H. acuticeps*, *H. adspersus*, *H. igbettensis*, *H. bengu*

The *Hyperolius viridiflavus* superspecies, where it is generally accepted that the group consists of several biologically distinct species.

The *Afrixalus fulvovittatus* complex, which probably consists of several cryptic species. In West Africa, the red-bellied dwarf is the most common.

The "Eastern Dwarf" *Afrixalus* are a bewildering group of small, savanna-living forms. The taxonomy used here is based on the work of the late Dr. John L. Collins.

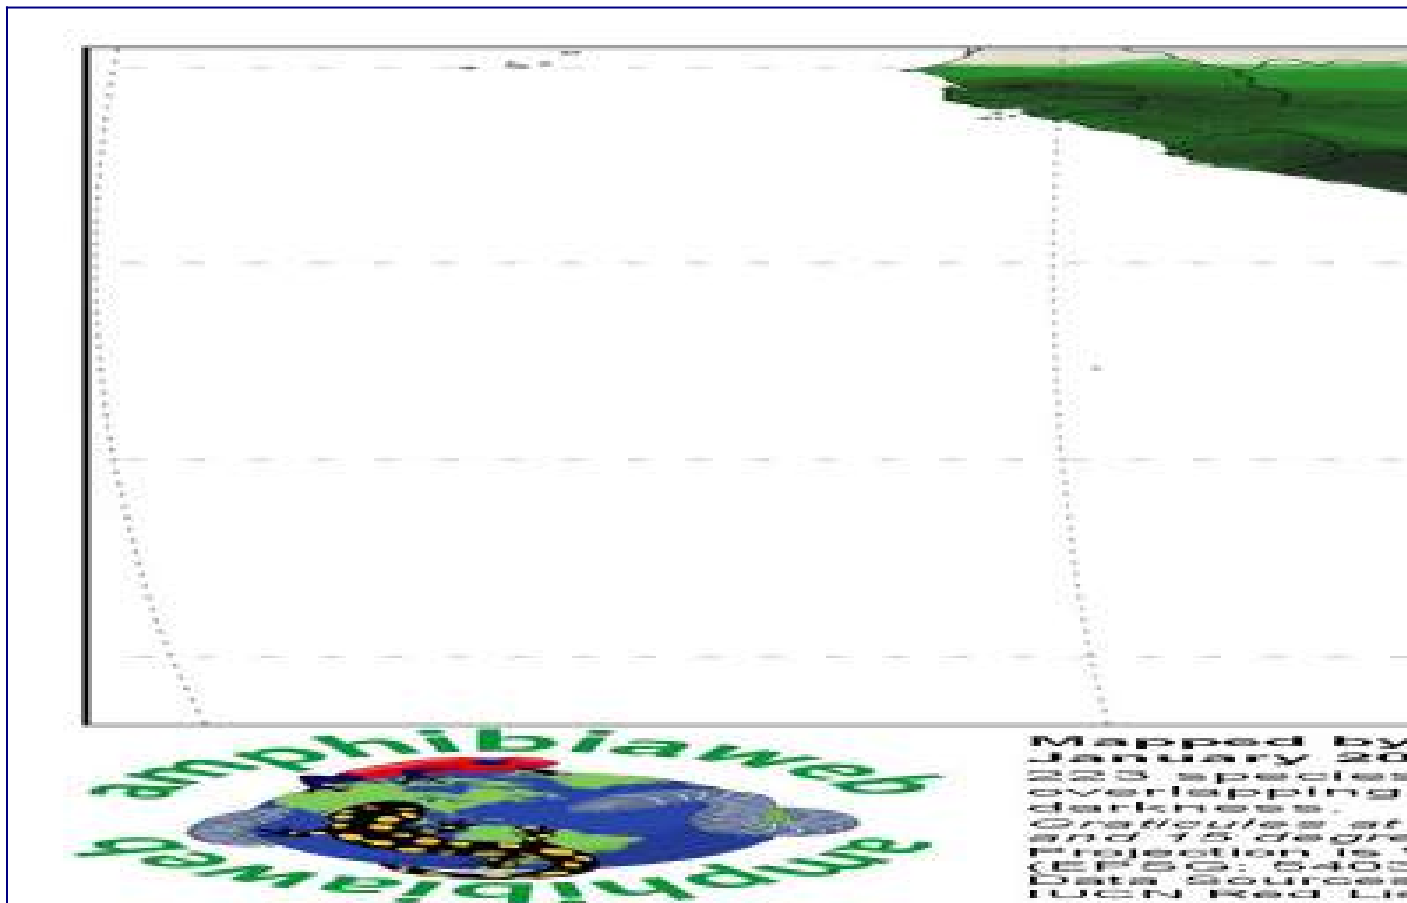

### News Highlight:

July 22, 2019: Despite the theory that sexually dimorphic traits under strong sexual selection lead to rapid speciation, the evolutionary origins of sexual dichromatism and how it relates to their diversification. Sexual dichromatism is a common trait in many groups of animals, but its evolutionary origins and how it relates to their diversification remain unclear.

Written by AmphibiaWeb

### Notable Family Characteristics

- Arboreal primarily, some terrestrial
- A range of habitats, forests and open savanna
- Diurnal in most
- Sexual dimorphism in some species, including striking dichromatism
- Morphological characters for this group are: 1) presence of unique gular gland; 2) nuptial pads absent; 3) vocalization unique to the genus
- Distribution limited to sub-Saharan Africa, Madagascar, and several islands, including the Seychelles

## Leiopelmatidae

3 species in 1 genus

***Commonly Called Tailed Frogs, New Zealand Frogs***

One of the more primitive of the living frog families, it shares many features generally thought to be inherited from Leiopelmatidae and the Tailed Frogs (Family Ascaphidae) of western North America. These are medium-sized frogs with broad heads, and smooth skin on the soles of their feet. The family includes four living species in the genus *Leiopelma* in New Zealand and the only native frog. However, these currently are found only in relictual populations on coastal islands, known, as early as the Early Miocene (16-19 ma), but many are from the Holocene (roughly 10,000 years ago) on the mainland; these probably went extinct about 1000 years ago. One of the largest fossil species is *Leiopelma waikatoensis* with a 100 mm snout-vent length compared to extant species, which reach a maximum of 50 mm snout-vent length.

Adults guard their clutches of direct-developing eggs. Young of *L. hamiltoni* and *L. archeyi* climb onto the back of the male during their development. Leiopelmatids are nocturnal and catch their prey by lunging at it, as they do not have protrusible tongues (unlike most frogs). They also use alternating kicks when swimming (unlike most frogs). This family does not vocalize, but it does call when molested.

*Ascaphus* and *Leiopelma* share many primitive characters, and there are apparently no derived characters that distinguish them from their relatives. However, DNA analysis consistently place Ascaphidae and Leiopelmatidae as closest relatives.

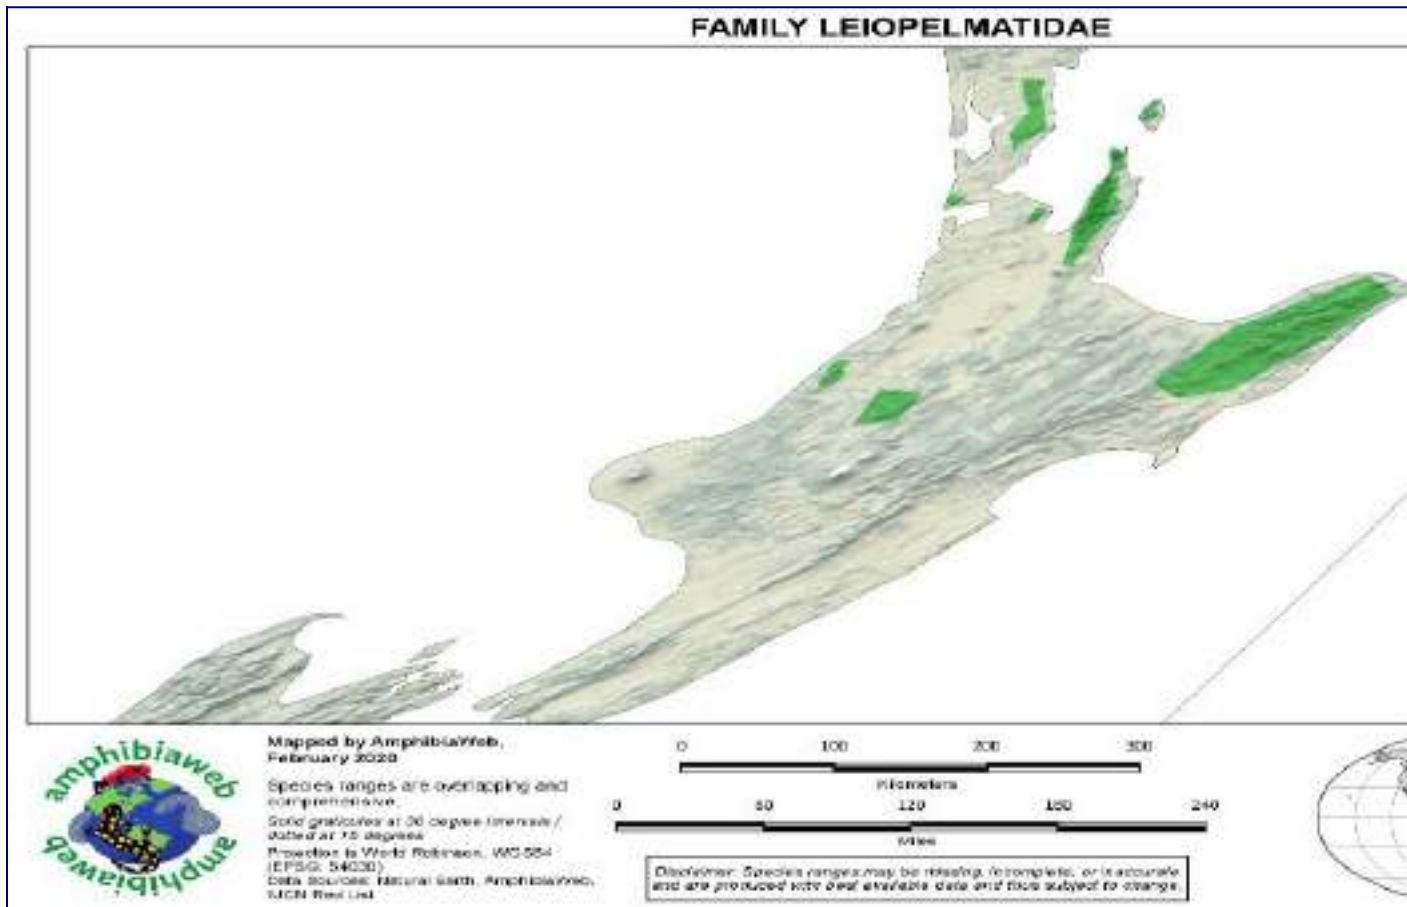

Three of the four species are listed as either Critically Endangered or Vulnerable by IUCN. New Zealand Threat Classification lists three to be 'Threatened' (*Leiopelma hamiltoni* as 'Nationally Critical', and *L. pakeka* and *L. archeyi* as 'Nationally Vulnerable'). *L. hochstetteri* is 'Declining'.

Written by AmphibiaWeb

## Notable Family Characteristics

- Cool forest creeks, streams, open seeps and ridges
- Terrestrial or semi-aquatic
- Nocturnal
- Inguinal amplexus
- Internal fertilization
- Unusually eggs are laid in damp undergrowth where they hatch into froglets. The male (*Leiopelma hamiltoni* and *L. archeyi*) may attend to the eggs until they hatch into froglets, which with tail still present, climb up on the male's back for the remainder of development; parental care seems absent in *Leiopelma hochstetteri*, where the larvae move into nearby water after hatching without parental involvement
- These frogs possess: 1) inscriptional ribs (cartilage embedded within abdominal muscle); 2) nine presacral vertebrae (as in Ascaphidae); 3) retention of caudalipuboischiotibialis ("tail-wagging") muscles (as in Ascaphidae). Other features: vertical pupils, broad heads, smooth-skinned soles on their feet, lack protrusible tongues
- Distribution limited to New Zealand

# Leptodactylidae

246 species in 13 genera

***Commonly Called Tropical Grass Frogs, Southern Frogs, White-lipped Frogs***

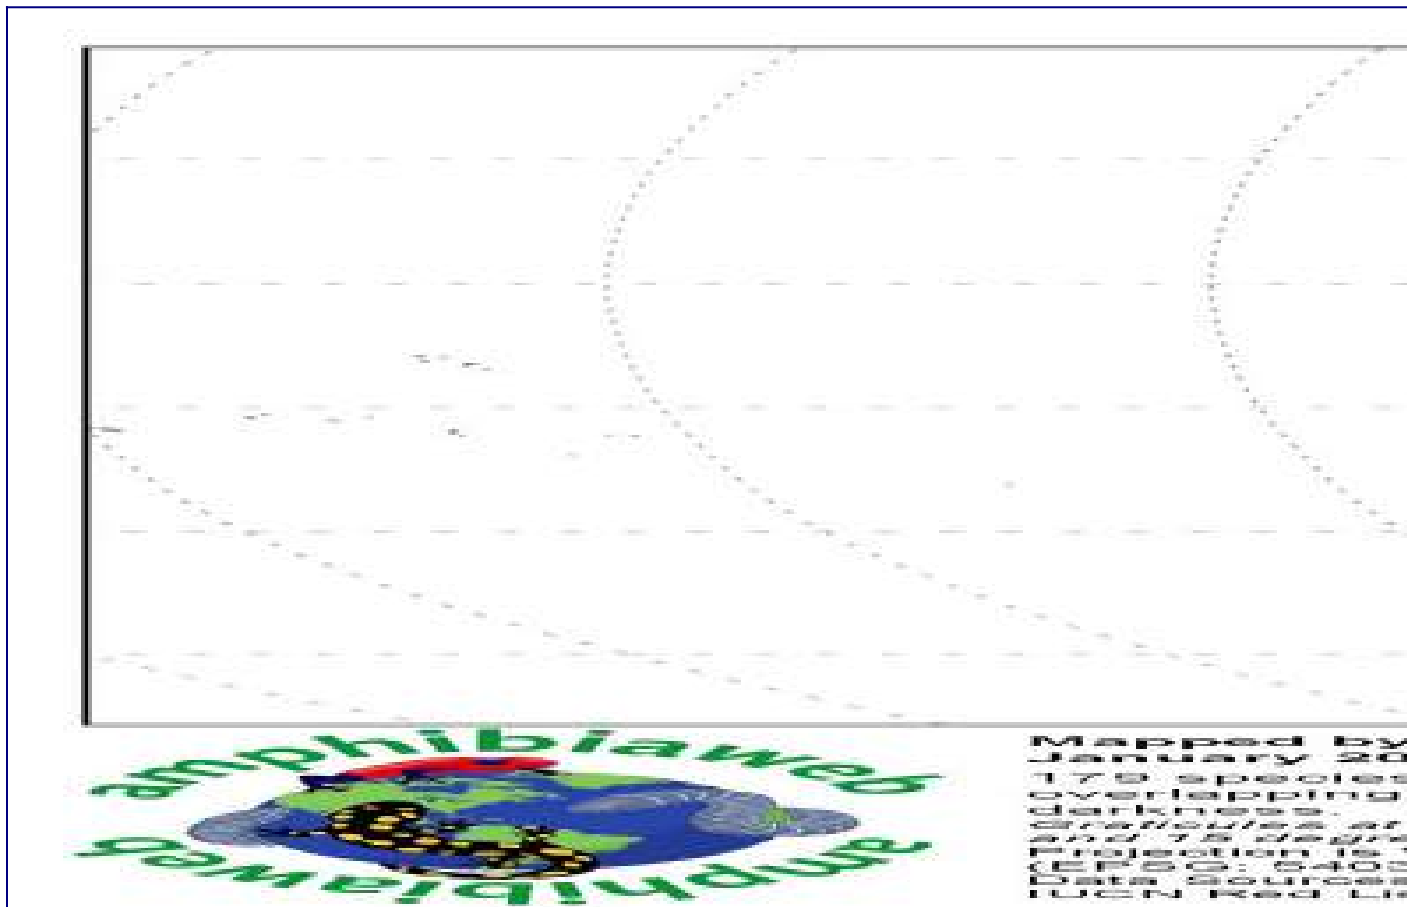

This large and diverse New World family has undergone substantial taxonomic revision (Frost et al. 2006; Gray 2006). Larval placement (surface of water, in treeholes, in foliage above streams, etc) are species-specific and vary widely.

Leptodactylids occur from southern Texas and Florida through Mexico and in South America. Some members

Written by AmphibiaWeb

## Notable Family Characteristics

- Terrestrial
- Tadpoles both aquatic and free-living and endotrophic
- *Leptodactylus* build foam-nests in a variety of micro-habitats that are species-specific
- Territorial; some species also guard larvae from potential predators (e.g., *Leptodactylus latrans*)
- Morphological features include: 1) paired palatines and frontoparietals in skull; 2) eight presacral vertebrae
- Distribution limited to southern North America (southern Texas, Florida, and Sonoran Mexico) through

## Mantellidae

291 species in 12 genera

## ***Commonly Called* Malagasy Poison Frogs**

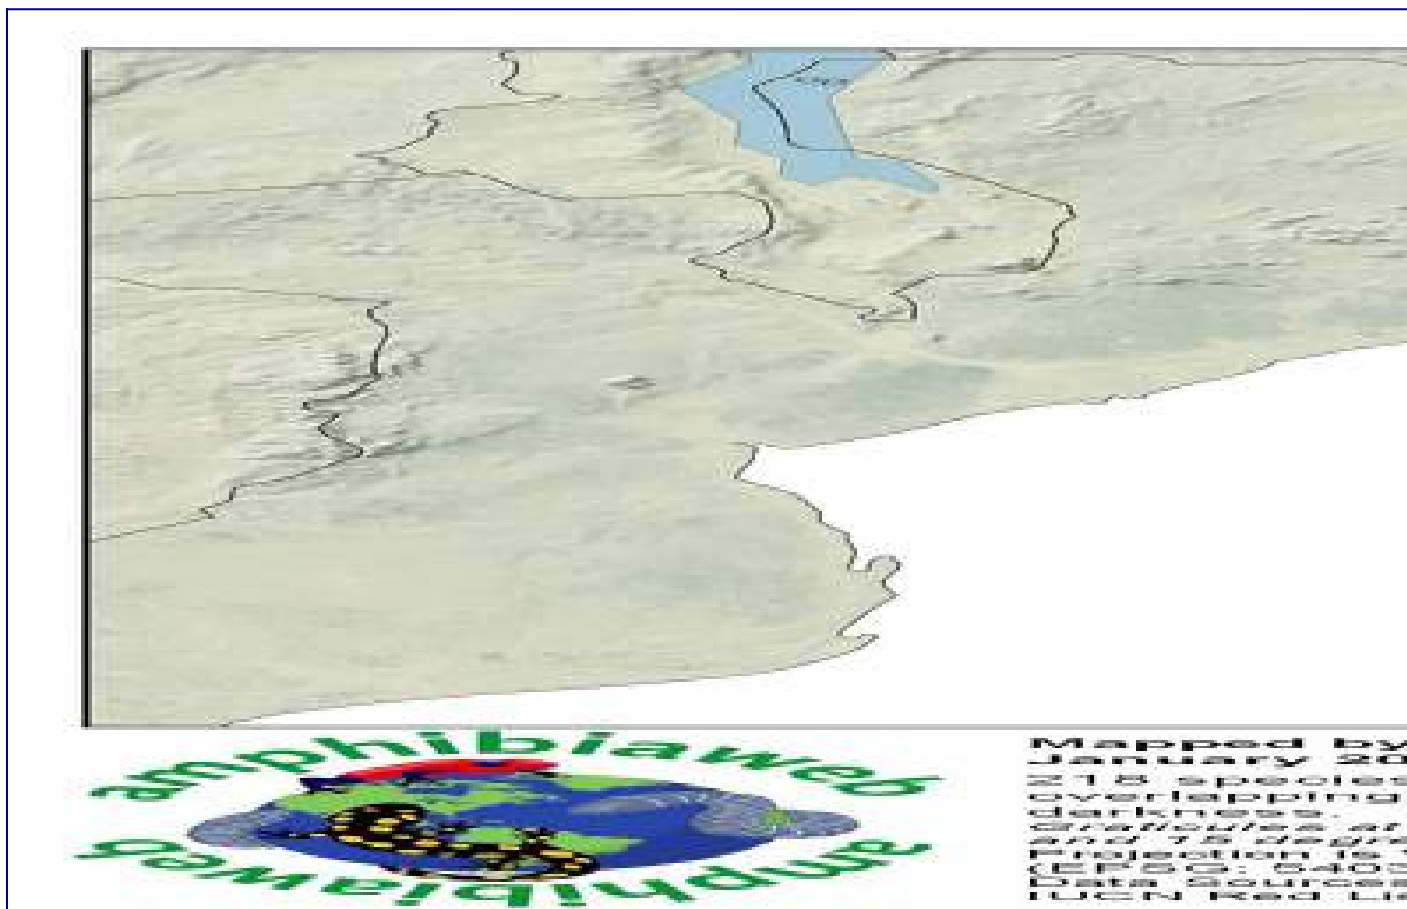

Mantellids are found only on the large island of Madagascar. The most famous members are of the genus *Mantella*. They vary from eggs deposited on vegetation with tadpoles that develop into streams, to terrestrial clutches whose tadpoles develop on land.

Mantellidae are sister taxon to Rhacophoridae.

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Terrestrial or arboreal
- Inhabits semiarid to wet tropical forests
- Axillary amplexus
- Reproductive behaviors are diverse
- Eggs laid terrestrially or on vegetation and aquatic larvae are either dropped from overhanging egg deposits or develop on land
- Genus *Mantella* known for its toxic skin alkaloids and aposematic coloration
- Distribution limited to Madagascar

## Megophryidae

366 species in 14 genera

***Commonly Called* Asian Horned Frogs, Asian Toads, Asian Toadfrogs, Leaf Litter Frogs**

These are the largest, most ecologically and morphologically diverse group of non-neobatrachian frogs in Sou

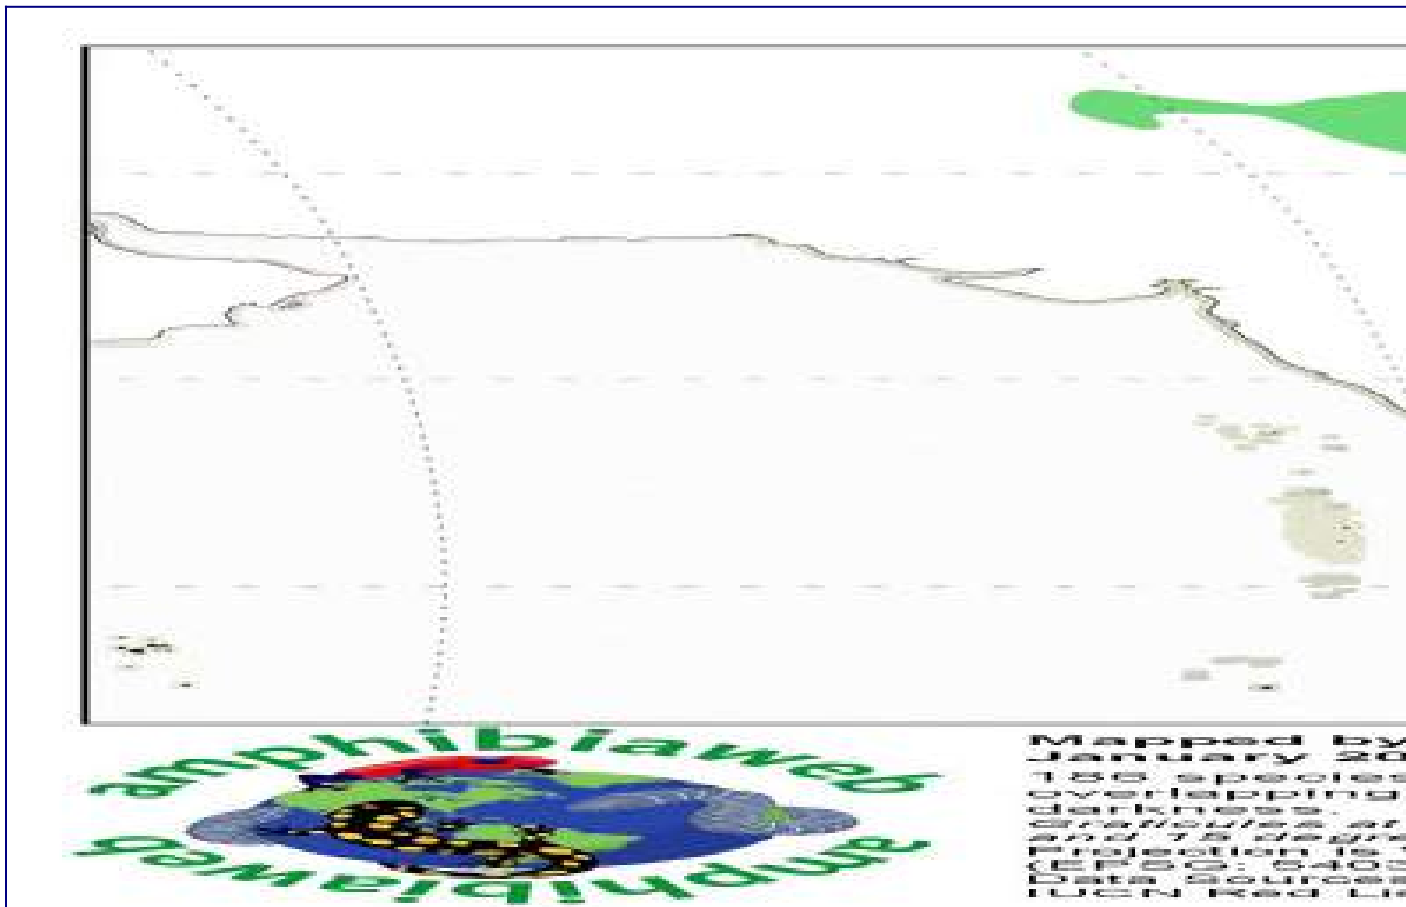

instead preferring to walk around. Tadpoles are aquatic and vary widely in natural history with many buccal a

Megophryid genera currently are taxonomically unstable with several studies disagreeing about the number of those subgenera to full genera.

Written by AmphibiaWeb, February 2022

### Notable Family Characteristics

- Inhabits forest floors or streamsides
- Terrestrial
- Nocturnal
- Eggs are deposited in water to hatch into aquatic tadpoles
- Morphological characters for this family are: 1) ceratohyals absent in adults; 2) intervertebral cartilage
- Distribution through South and Southeast Asia, extending through India, Pakistan, Myanmar (Burma),

## Micrixalidae

24 species in 1 genus

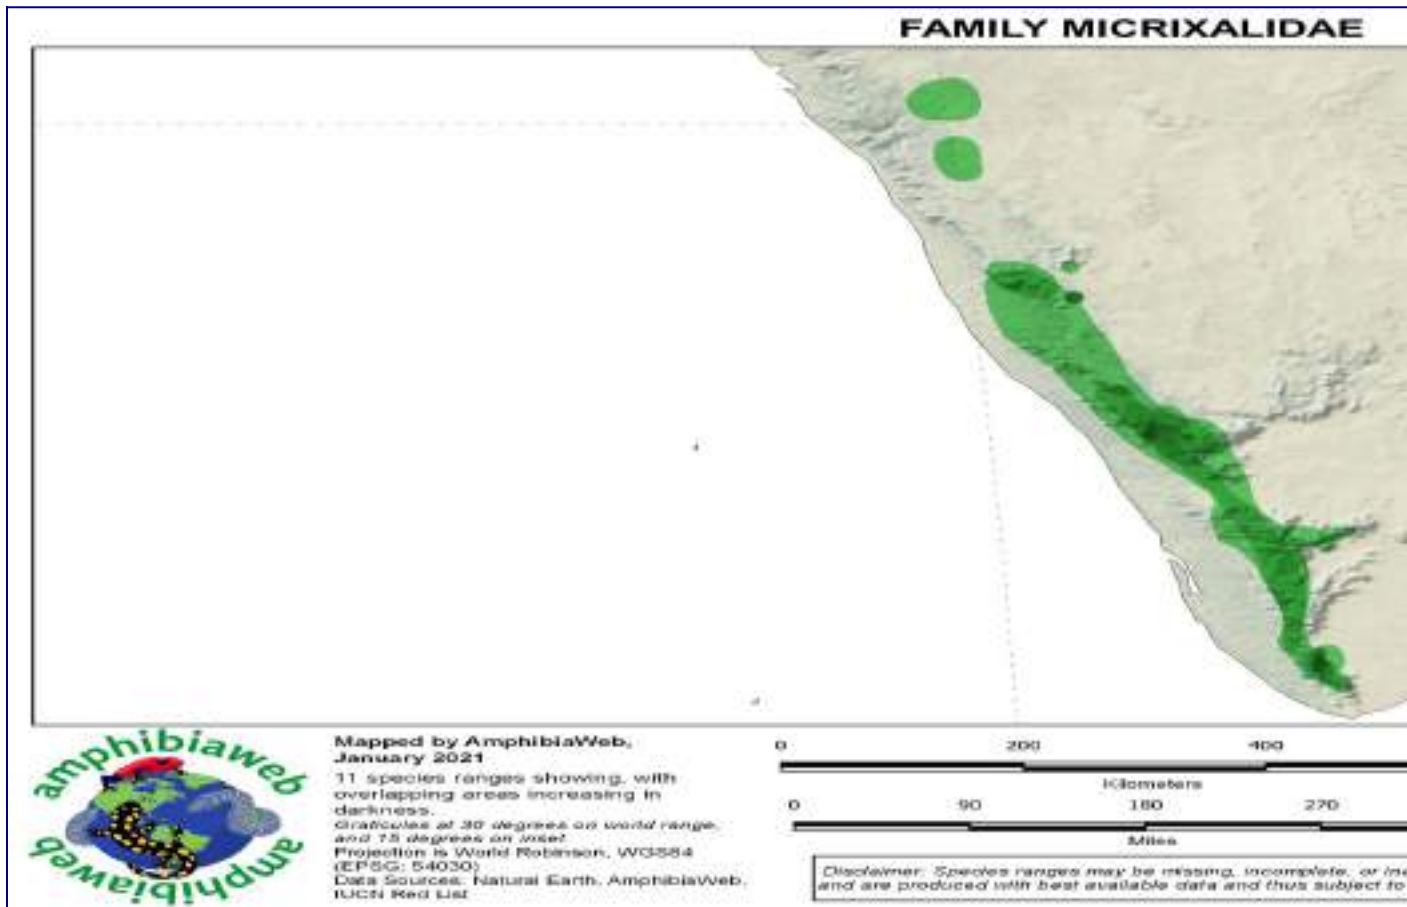

### ***Commonly Called Tropical Frogs, Indian Dancing Frogs***

These frogs are found exclusively in the Western Ghats of India, similar to the Nyctibatrachidae, and likewise mostly from *Micrixalus saxicola*, is fascinating; males contest for nesting sites by foot-flagging displays when foot. It has been documented in several species (*Micrixalus elegans*, *M. fuscus*, *M. herrei*, *M. kottigeharensis*, *uttaraghati*). Females lay their eggs underground or bury them where they hatch. In *Micrixalus herrei* at least maneuver through the substrate.

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Inhabits streams, stream banks in tropical rainforest
- Males engage in foot-flagging displays to establish nesting sites
- Eggs laid underground with fossorial tadpoles
- Morphological characters include: Finger and toes with dermal fringes, and discs dilated with dorsoternally oval; webbing absent on hand; pineal ocellus present, vomerine teeth and ridge absent.
- Distribution limited to Western Ghats of India

## Microhylidae

766 species in 59 genera

### ***Commonly Called* Narrow-mouthed Frogs**

A large, complicated group, with up to 60 genera and over 700 species. These are mostly fossorial or terrestrial.

Asia (India and most of southeast Asia, to New Guinea), northern Australia, sub-Saharan Africa and Madagascar. Southeast Asia (van der Meijden et al. 2007). The microhylids display a variety of reproductive strategies including direct development. Species are similar in body plans through the presence of stout hind legs, short snouts, and globular bodies. One of the most colorful microhylids is *Dyscophus antongilii*, known as the Tomato Frog due to its rounded body (which bears a resemblance to a tomato) and bright red color; this frog is native to Madagascar.

Bossuyt and Roelants (2009) proposed a taxonomy for anurans that would elevate microhylid subfamilies to family rank based on divergence time (late Cretaceous) based on analysis of molecular data. Given that time estimates are subject to error, Bossuyt and Roelant's statement that "molecular time estimates for some anuran nodes are notably older than those for other nodes" led them to retain these microhylid clades as subfamilies rather than families.

Van der Meijden et al. (2007) found that the genus *Otophryne* was basal to microhylids and excluded it from the subfamily Otophryninae; we have here followed Frost (2009) in resurrecting the subfamily Otophryninae to hold this genus and other genera *Adelastes*, *Altigius*, *Arcovomer*, *Hyophryne*, *Melanophryne*, *Myersiella*, *Relictivomer*, *Stereocyclops*, and *Stumpffia*. South American microhylids, although neither Frost (2006) nor van der Meijden et al. (2007) chose to assign them to a subfamily. Van der Meijden (2007) in leaving the Indonesian/Malaysian genera *Gastrophrynoides* and *Phrynellia* unassigned. *Synapturanus*, which Van der Meijden et al. explicitly excluded from Gastrophryninae. For the newly described genus *Stumpffia*, provisionally assigning this genus to the subfamily Asterophryninae.

The subfamilies of Microhylidae recognized by AmphibiaWeb include:

1. Adelastinae (South America)
2. Asterophryninae (Australia, mainly Papua New Guinea; direct development)
3. Cophylinae (Madagascar)
4. Dyscophinae (Madagascar)
5. Gastrophryninae (South America)
6. Hoplophryninae (Africa)
7. Kalophryninae (Asia)
8. Melanobatrachinae (Asia)
9. Microhylinae (Asia; this group has both endotrophic larvae and feeding, free-swimming larvae)
10. Otophryninae (South America)
11. Phrynomerinae (Africa)
12. Scaphiophryninae (Madagascar)

### News Highlight

December 14, 2017: New species of amphibians continue to be described at a rate of about 2.9 species per year. Some of these species are direct developers that develop directly without tadpoles and they typically have small to very small geographic ranges. Such is the case with *Stumpffia* from Madagascar, a clade of mainly small to miniaturized frogs (a few are much larger than the others). A new species of *Stumpffia* was described based on a multidimensional analysis. The genus is highly diversified genetically as well as morphologically. (See [Stumpffia on AmphibiaWeb](#)). Regrettably, 18 of the total of 41 species in this genus are recommended as Endangered. The new species tend to come from what are literally the last wild places. (DW)

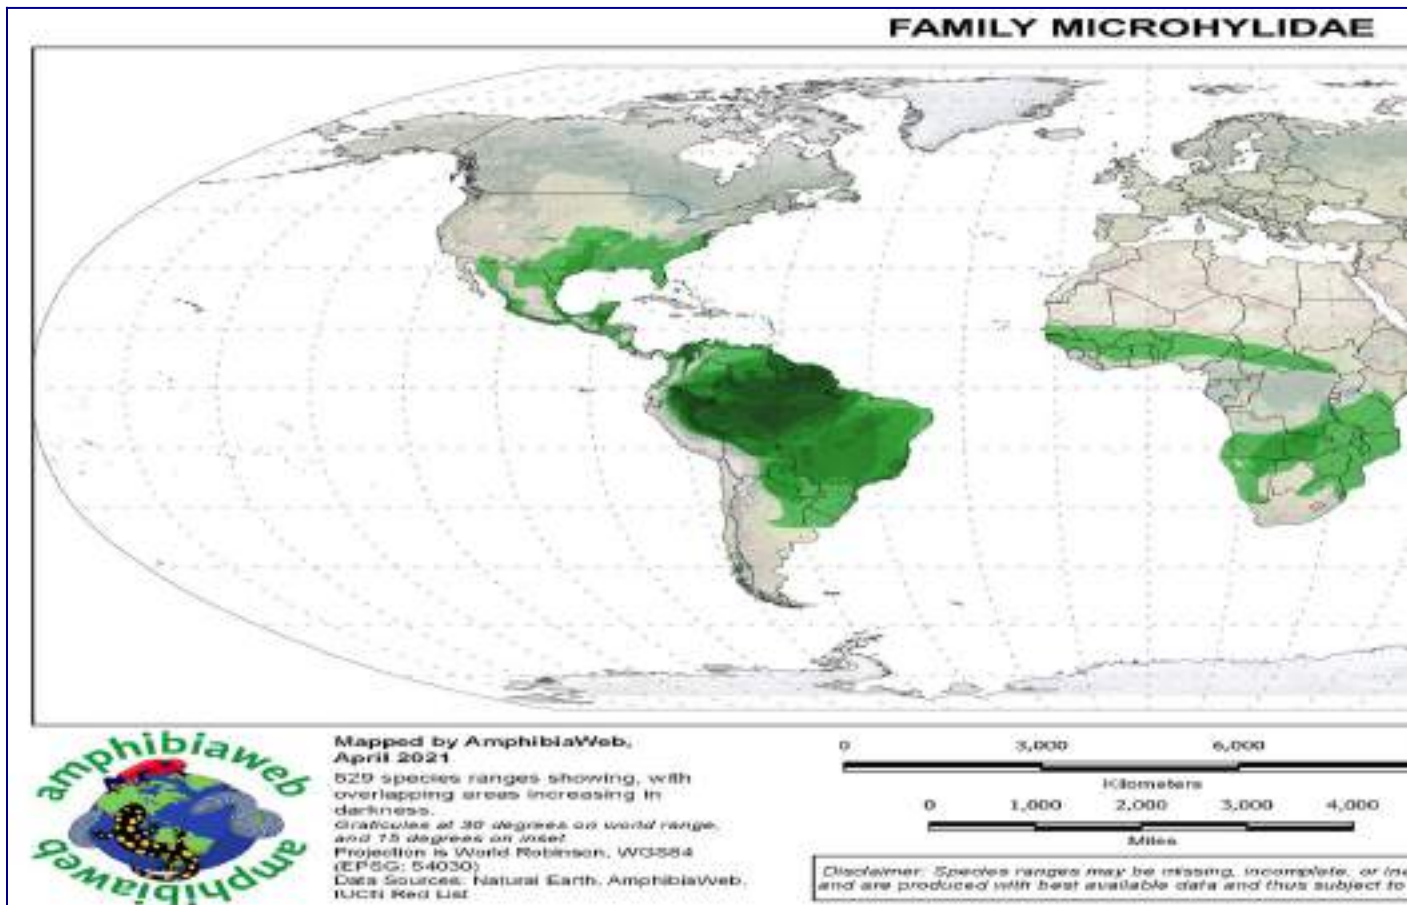

Written by AmphibiaWeb

### Notable Family Characteristics

- Terrestrial, aquatic, arboreal and some fossorial species, including cave-dwelling (*Siamophryne troglodytes*)
- A variety of habitats, from deserts to wet tropical rain forests

- A variety of reproductive strategies including aquatic larvae, larvae without mouthparts and direct development
- Morphological characters for this group are: 1) cornified denticles absent in larvae; 2) glottis fully exposed in larvae; 4) ventral velum divided medially in larvae; 5) two or three palatal folds in adults. Generally slender bodies with a generalized teardrop shape
- Distribution widely in the Americas, Asia (India and most of southeast Asia, to New Guinea), northern Australia, and a number of species in Madagascar and Southeast Asia

## Myobatrachidae

138 species in 22 genera

**Commonly Called Australian Water Frogs, Australian Froglets, Toadlets, Ground Frogs,**

This assemblage of frogs is made up of 21 genera, distributed in Australia, Tasmania, and New Guinea. They have life histories vary from having aquatic larvae to terrestrial direct developing to eggs/tadpoles which are brooded (e.g. *darlingtoni*). Members of the now extinct genus *Rheobatrachus* were able to 'swallow' their eggs and brood them in their stomachs. Different morphotypes exist within this family, from squat, short-legged, thick-snouted forward body forms to semi-aquatic body forms. Much is still to be discovered about their natural histories.

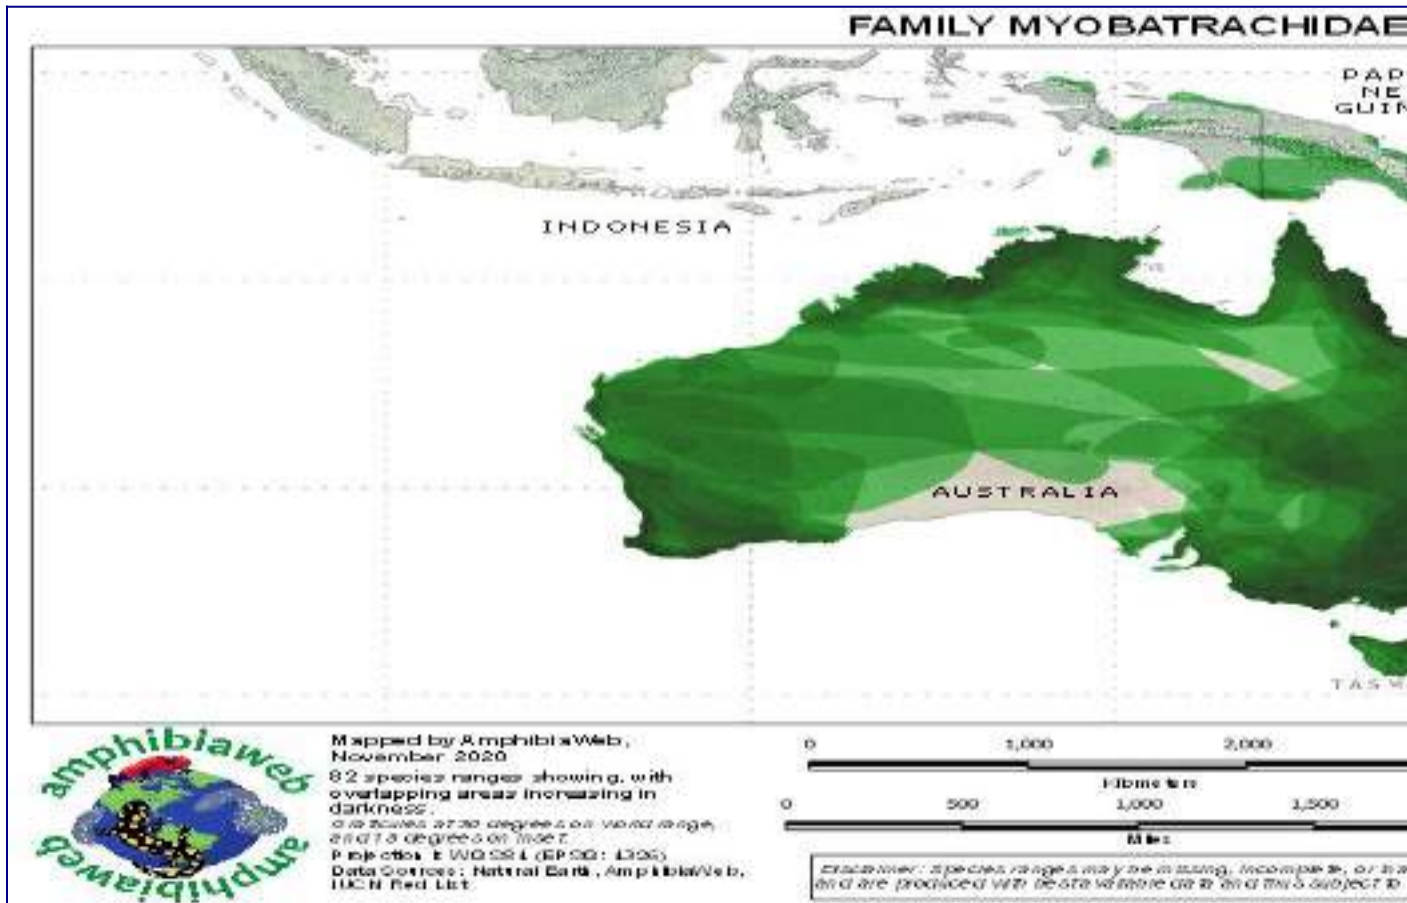

Many species are endangered and several are listed as extinct, including the gastric-brooding species of genus *Rheobatrachus*.

Written by AmphibiaWeb

### Notable Family Characteristics

- Terrestrial most, and a few fossorial

- Inhabits a variety of forests, open grasslands, streamsides
- A variety of reproductive modes, especially development from aquatic larvae to terrestrial direct development; tadpoles in specialized pouches or in the stomachs of the parent
- Morphological characters for this family are: 1) lack of fusion of the first two presacral vertebrae; 2) broad shape of alary processes of the hyoid (except in *Rheobatrachus*); 3) small or absent finger/toe discs; 4) periaxial sheath enclosing the axial fiber of the sperm flagellum.
- Distribution limited to Australia, Tasmania, and New Guinea

## Nasikabatrachidae

2 species in 1 genus

### ***Commonly Called Purple Frog, Pignosed Frogs***

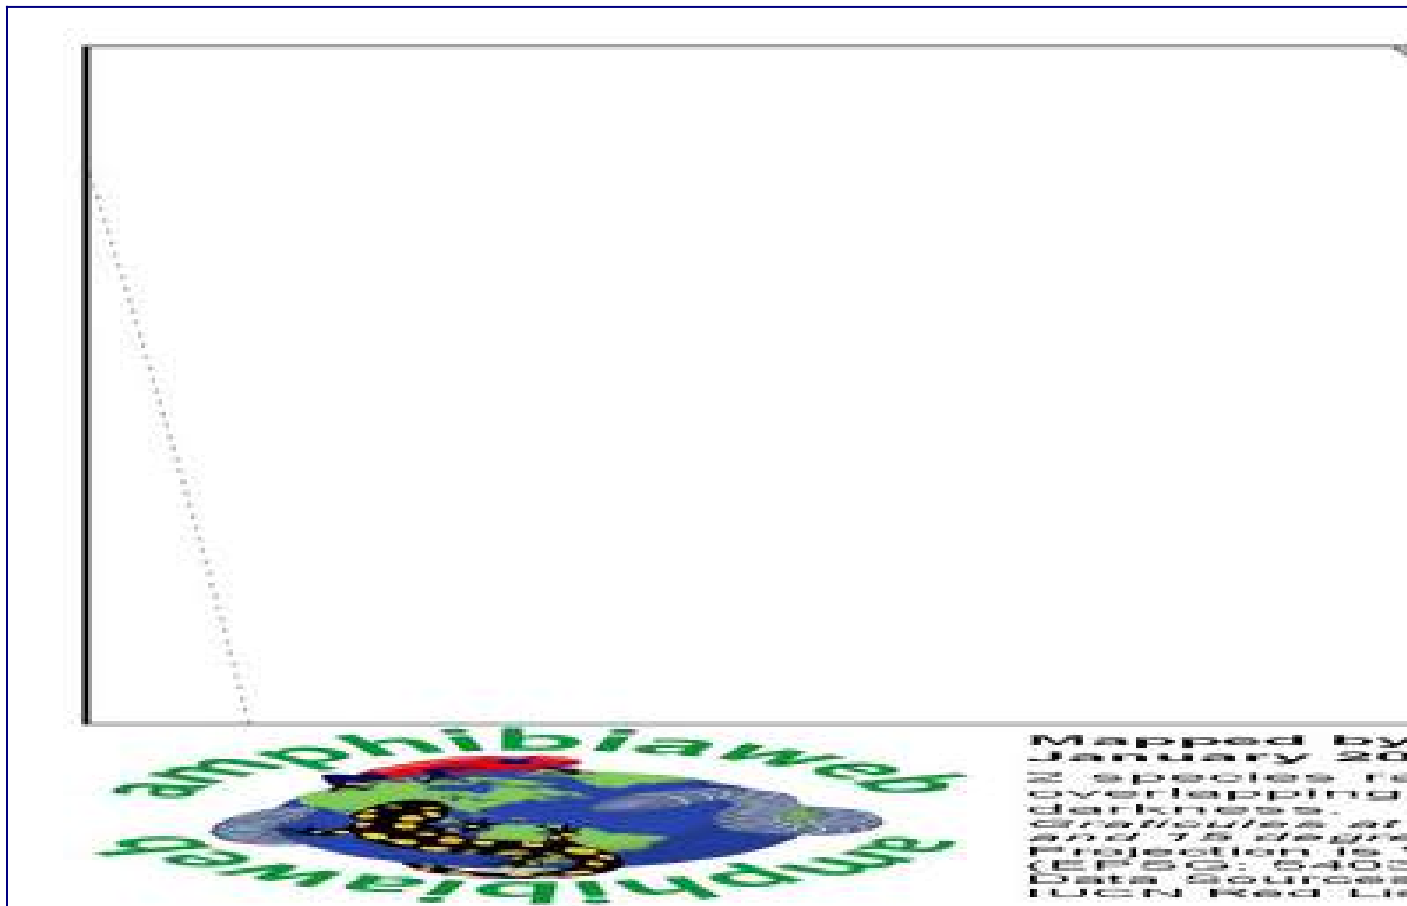

A recently discovered frog family in 2003, nasikabatrachids are restricted to southern India in the Western Ghats.

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Morphological distinguished by: 1) smooth, thick skin; 2) small heads; 3) a long snout with a white, knobby tip; 4) a large, white, metatarsal tubercle; 5) highly ossified skull; 6) no tympanum, no columella
- Fossorial
- Breeds in the heavy rains of monsoon season
- Feeds mainly on termites
- Inguinal amplexus
- Tadpoles are aquatic

- Distribution only known from the southern Western Ghats in India

Cartography Credit: Zoe Yoo, UC Berkeley

Range maps sources: AmphibiaWeb, UC Berkeley, and IUCN RedList

# Neblinaphrynidae

## 2 species in 1 genus

Known only from the elevated mountaintop (tepui) called the Neblina massif in northern Brazil, the family Neblinaphrynidae was described in 2023 by Fouquet et al. It is distinguishable from all other families in Brachycephaloidea mostly on the basis of molecular characters (Fouquet et al 2023).

This family represents an ancient lineage of frogs known only from an isolated massif which Fouquet et al (2023) characterize as 'museums' or evolutionary refugia for "the diversification of Brachycephaloidea and of Neotropical biotas more broadly, in line with the influential 'Plateau theory' or 'Lost World Theory' (named after Sir Arthur Conan Doyle's famous story of the same name). This postulates that fragmented areas of repeated geographic, climatic, or other environmental isolation over long periods of time may favor allopatric speciation and maintain lineages through time.

Written by AmphibiaWeb

## Notable Family Characteristics

- Morphological characters include: presence of arciferal pectoral girdles, partially fused calcanea and astragali, absence, or at least highly vestigial, septomaxillae and pointed terminal phalanges
- Currently monotypic with one known species
- All known specimens found above 2,000 m asl, and mostly around 2,600 m, on Neblina massif in Brazil

# Nyctibatrachidae

38 species in 3 genera

## ***Commonly Called* Night Frogs, Fanged Frogs, Wrinkled Frogs, and Water Frogs**

This family is known only from the Western Ghats of India and from Sri Lanka. Several studies confirm the mountains in India in the mid to late Cretaceous (Van Bocxlaer et al. 2012).

Most species from this family are in the genus *Nyctibatrachus*, which occur in the Western Ghats of India. *Lankanectes*

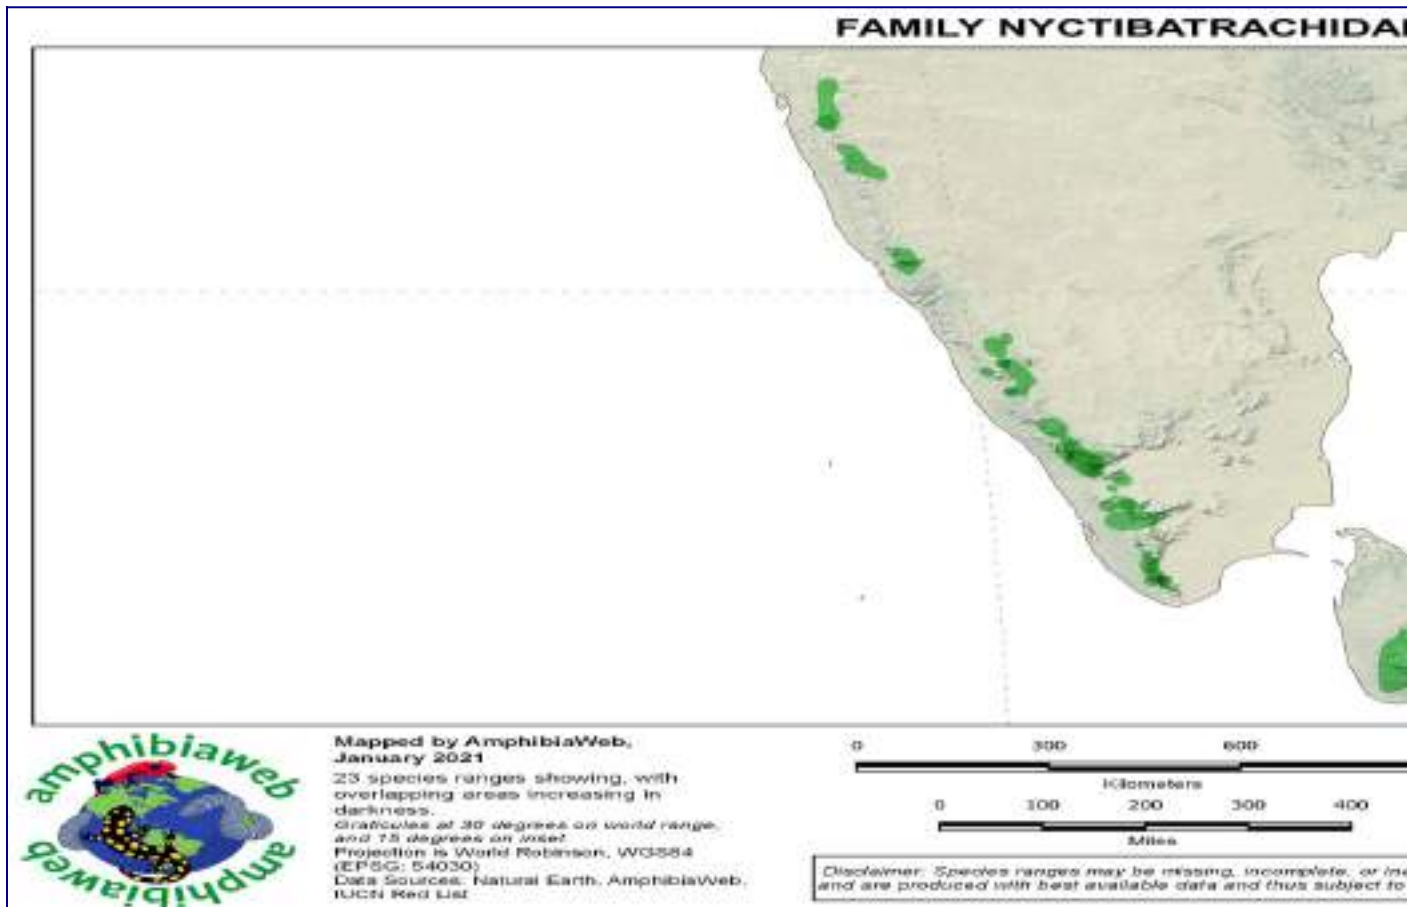

### **News Highlight**

February 27, 2017: The Night Frogs, Nyctibatrachidae, is a small, ranoid family endemic to the Western Ghats of India. Small sized species (up to more than 80 mm body size) have been primarily stream-dwelling. Research in the family has been slow from several families being announced at regular intervals, and it is widely recognized as an important but understudied group. New nyctibatrachids, but what is special about this find is the first miniaturized species in the family. Found in damp forest floor leaf litter and marsh vegetation. Apparently all have a tadpole stage. They have a unique insect-like call, secretive habits and different habitat preferences, and they are locally abundant. Nevertheless, they face human influences. The authors estimate that about one-third of nyctibatrachids are threatened with imminent extinction.

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Found in wet, marshy habitats or are restricted to rocky torrents in montane and sub-montane evergreen forests. *Lankanectes* may be found in slow-moving streams
- Aquatic
- Some species may use dorsal straddle amplexus as reported in *Nyctibatrachus humayuni*
- *Nyctibatrachus* males possess femoral glands and mandibular fangs
- Hidden tympanum, wrinkled skin, longitudinal skin folds on dorsum
- Nocturnal, or presumed to be
- Distribution limited to the Western Ghats of India and Sri Lanka

# Odontobatrachidae

5 species in 1 genus

## ***Commonly Called* Torrent-frogs**

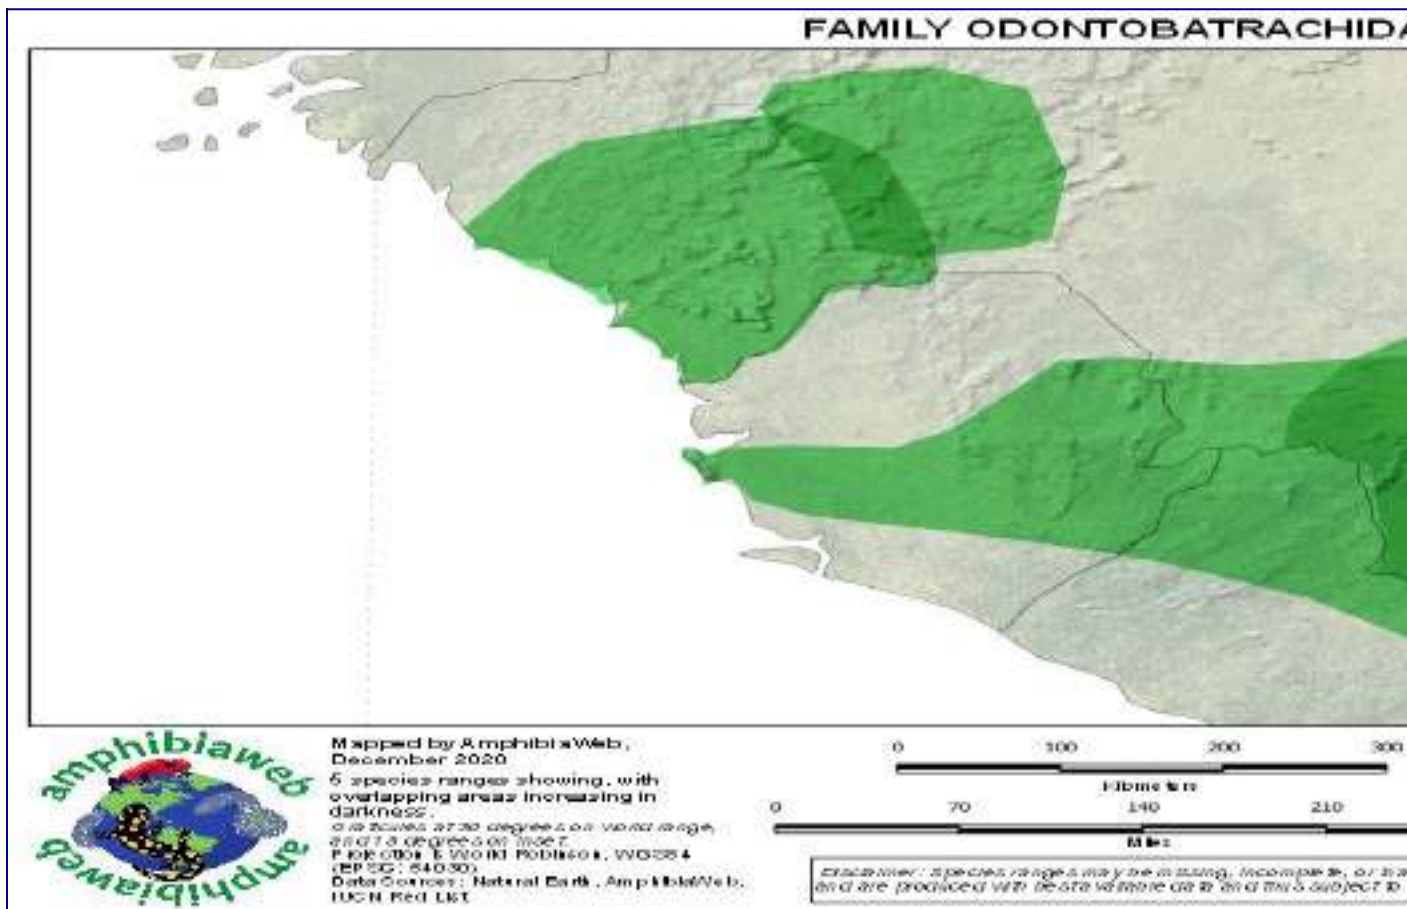

These uniquely West African species were previously in the Petropedetidae (*Petropedetes*) until Barej et al. (2015) reclassified them based on morphological and molecular characteristics. Much natural history and biology is unknown about this group.

Written by AmphibiaWeb

## **Notable Family Characteristics**

- Tusk-like odontoids (fanglike structures) on the lower mandible as well as curved and pointed pre- and post-mental teeth
- Indistinct tympanum, granular skin with ridges, extensive webbing,
- Males with femoral glands, large pair of external vocal sacs, nuptial pads
- Associated with streams or rapids
- Distribution limited to West Africa, including Upper Guinean forests in Guinea, Sierra Leone, Liberia, Ivory Coast, and Ghana

Cartography Credit: Zoe Yoo, UC Berkeley

Range maps sources: AmphibiaWeb, UC Berkeley, and IUCN RedList

# Odontophrynidae

54 species in 3 genera

***Commonly Called* Smooth Horned Frog, Ground Frogs, Escuerzo or Forest Frogs**

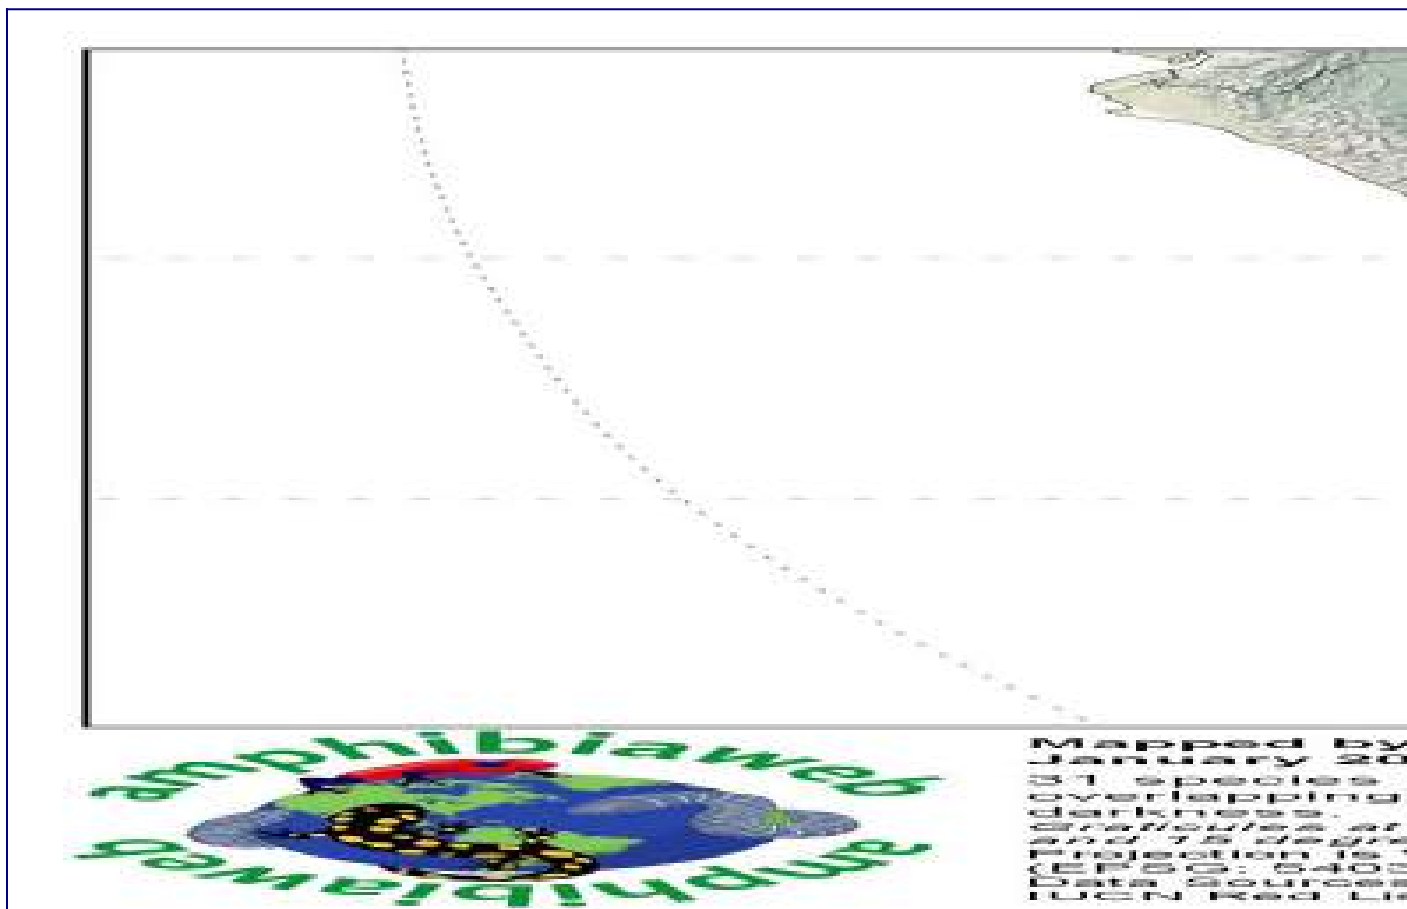

These small to medium frogs are robust bodied with generally round, wide, sometimes large, heads. Species r

The current organization of this family was first recognized in 2011 (Pyron and Weins).

Written by AmphibiaWeb

## **Notable Family Characteristics**

- Terrestrial in a variety of habitats from open grasslands to marshes to forests
- Some species are fossorial
- Some species are explosive breeders
- Lays eggs in water, which hatch into tadpoles
- Distribution limited to southern and eastern South America

## Pelobatidae

6 species in 1 genus

### *Commonly Called Spadefoot Toads*

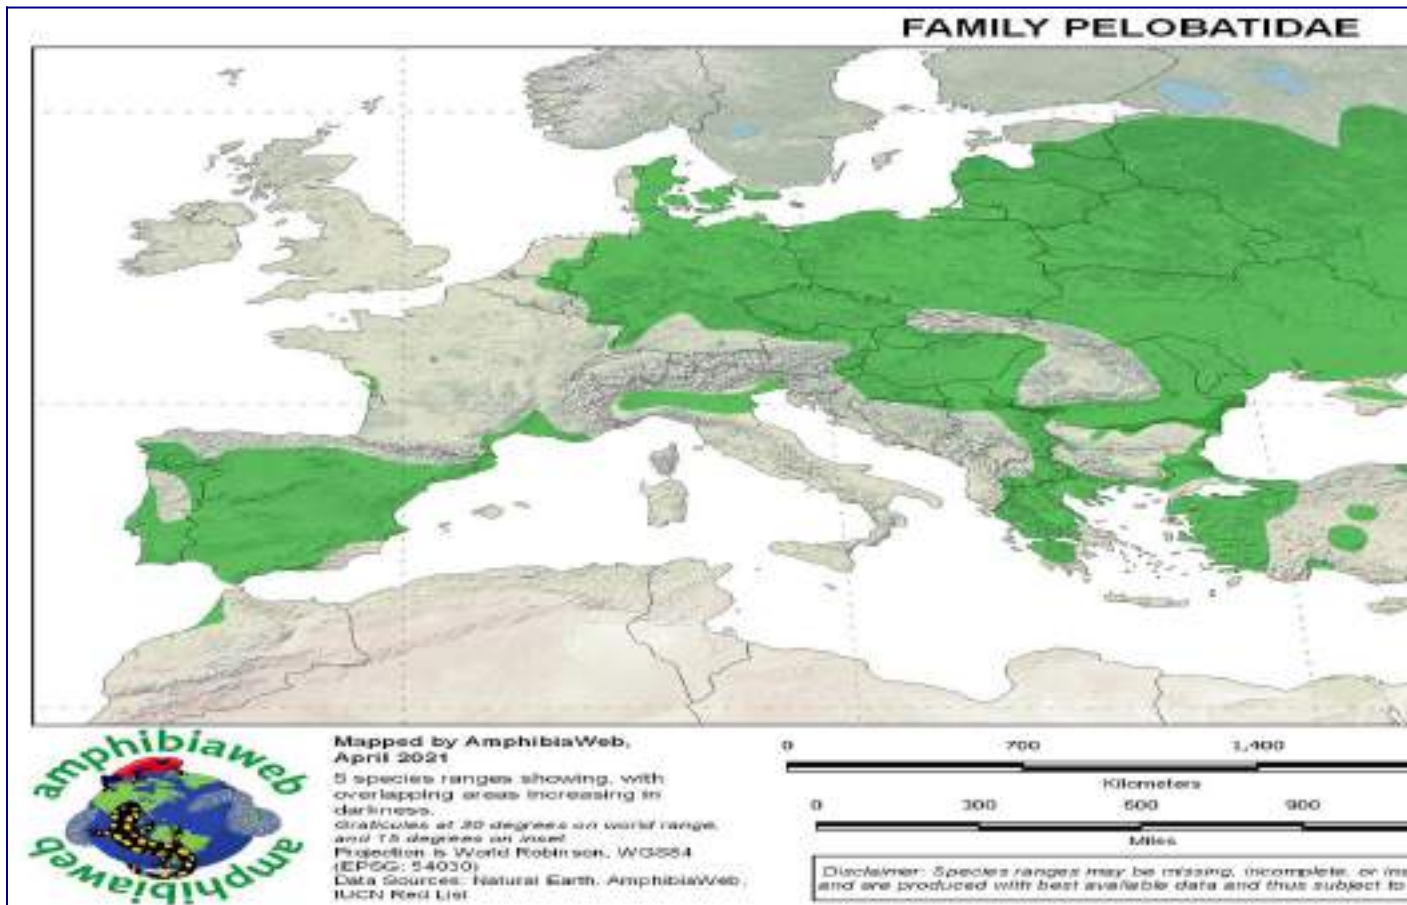

This family was revised, to consist entirely of the genus *Pelobates*, which occurs in western Eurasia and north the family Scaphiropodae, in which the genera *Spea* and *Scaphiopus* occur throughout North America. They are of a keratinized "spade" on each hind foot which are used in burrowing. While all spadefoot toads were once reveal that *Pelobates* is closer to Mygophryidae than Scaphiropodae.

Pelobatids inhabit arid habitats and are known as explosive breeders due to their seeming to explode out of the tadpoles that develop rapidly in temporary ponds, even in desert regions. They have short legs and stocky bodies.

Written by AmphibiaWeb

### Notable Family Characteristics

- Terrestrial, mostly fossorial
- Inhabits deserts and other arid regions
- Breeding is highly seasonal, and large numbers surface with rains to breed and lay eggs in temporary v
- Morphological characters for this group are: 1) sacrocygial (sacrum and urostyle) joint fused; 2) from exostosed (with bony growths); 3) metatarsal spade supported by well ossified hallux; 4) palatines ab pectoral girdle arciferal with distinct sternum and omosternum; 6) astragalus and calcaneum fused onl Other features are stocky bodies with vertical pupils
- Distribution limited to western Eurasia and northwestern Africa

## Pelodytidae

5 species in 1 genus

### *Commonly Called Parsley Frogs*

These frogs are small species with bulging eyes and are known as "parsley frogs" due to the coloration of *Pelodytes punctatus*. They may become diurnal during the breeding season when males call underwater and breed in water bodies where

Pelodytidae was formerly contained within Pelobatidae; however, it was elevated to its own family mainly because of its unique morphology in frogs (only also known in centrolenid frogs). Recent molecular work shows this family as sister to

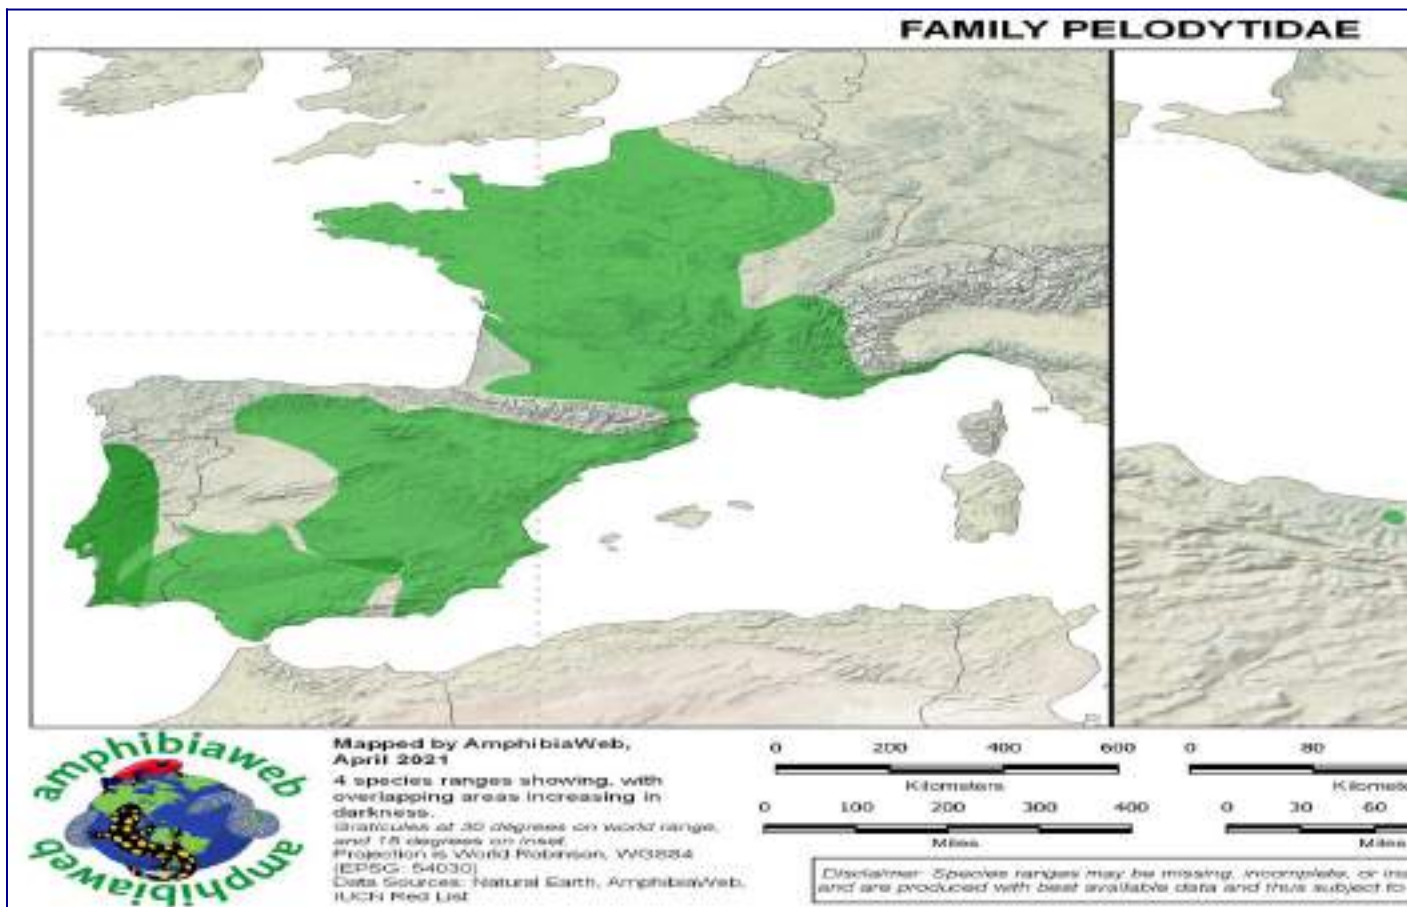

Written by AmphibiaWeb

### Notable Family Characteristics

- Terrestrial
- Nocturnal except for the breeding season when they may be active during the day
- Eggs laid in water to hatch into tadpoles

- Morphological characters include: 1) fused astragalus and calcaneum (also in some centrolenids); 2) p in the hyoid apparatus (also in *Rhinophrynus* and paleobatrachids); 3) fused vertebrae I and II; 4) three
- Distribution limited to western Europe, especially in the Iberian Peninsula, and in western Asia

## Petropedetidae

13 species in 3 genera

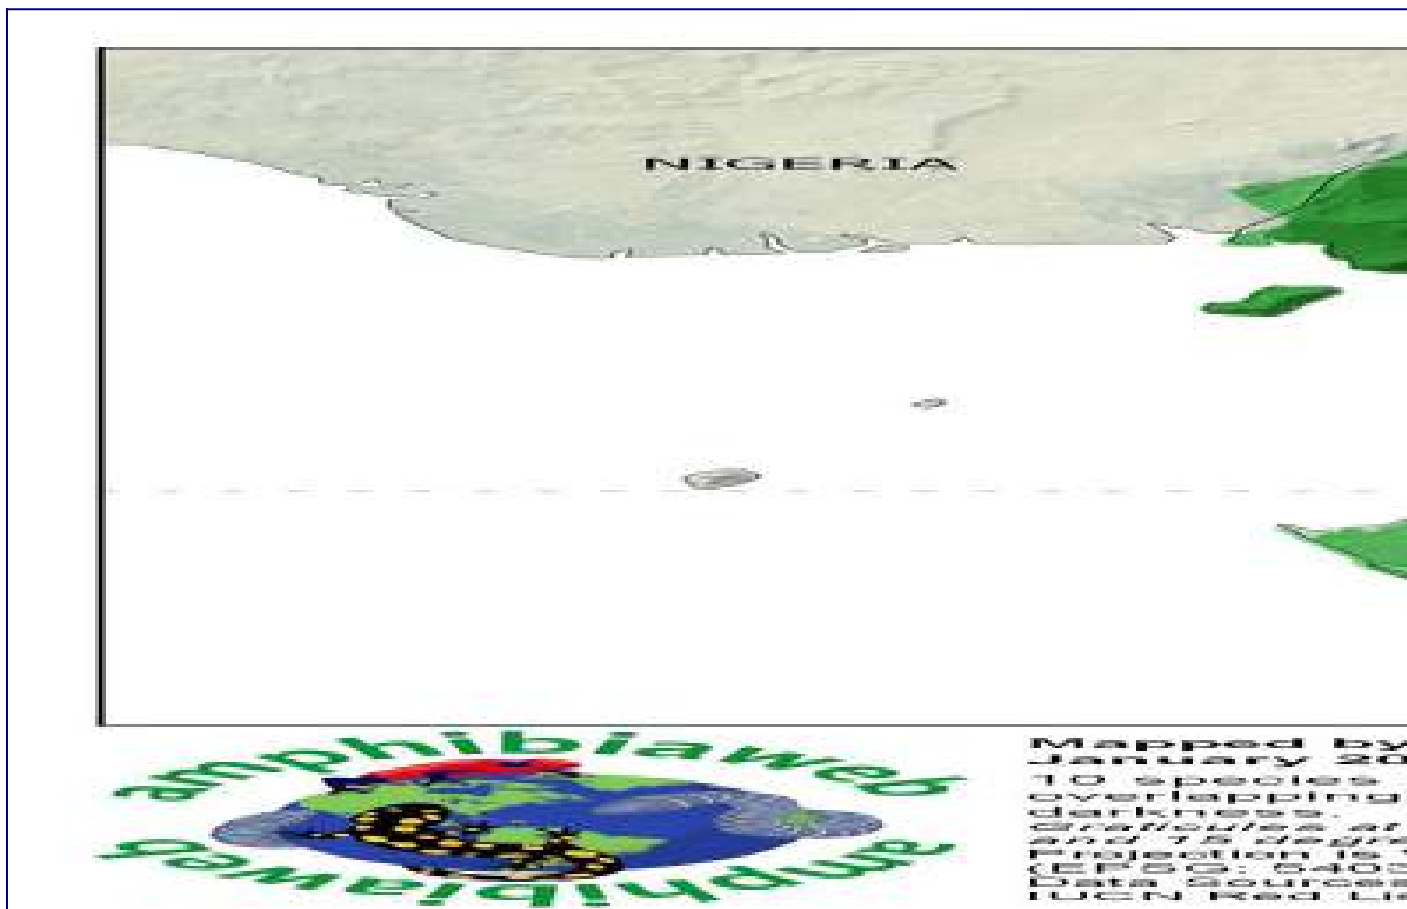

***Commonly Called African Torrent Frogs, Water Frogs, Rocky River Frogss***

These small to medium compact frogs inhabit the spray zone of streams and waterfalls in Africa. They are known for their loud, croaking calls.

Written by AmphibiaWeb

### Notable Family Characteristics

- Found in the spray zone of forest or savannah streams and waterfalls
- Many species appear to be diurnal
- Males of many species appear to be sexually dimorphic, with features such as femoral glands, enlarged vocal sacs, and distinct tympanum
- Distribution limited to a small portion of Central Africa and disjunct occurrences in East Africa

## Phrynobatrachidae

100 species in 1 genus

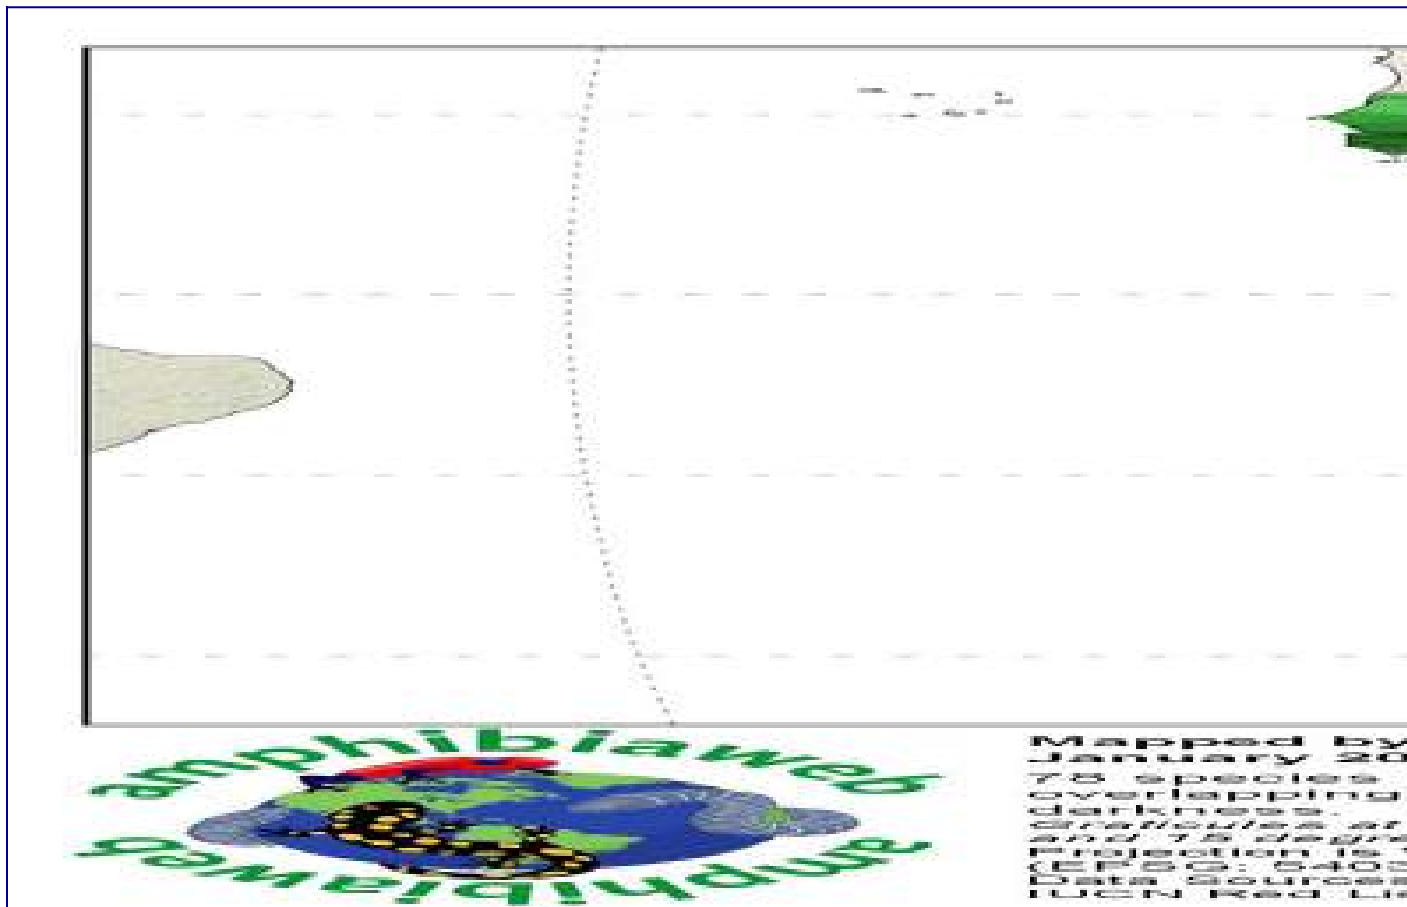

### Commonly Called Puddle Frogs

This is a speciose family currently consisting of a single genus, all found in a variety of habitats in sub-Saharan Africa.

Written by AmphibiaWeb

### Notable Family Characteristics

- Found in a variety of habitats, from savannah to primary forests
- Morphological characteristics include: 1) medial lingual tubercle; 2) firmisternal pectoral girdle; 3) no T-shaped terminal digits without discs.
- Most species are known to lay eggs in water, which hatch into tadpoles
- Tadpoles have a single row of labial teeth
- Reproductive modes vary widely
- Some species are highly polymorphic in coloration and pattern
- Distribution limited to sub-Saharan Africa

## Pipidae

41 species in 4 genera

### ***Commonly Called Tongueless Frogs, African Clawed Frogs, Suriname Toad***

Members of this family can be found in almost every kind of water body in Africa and South America. Two m

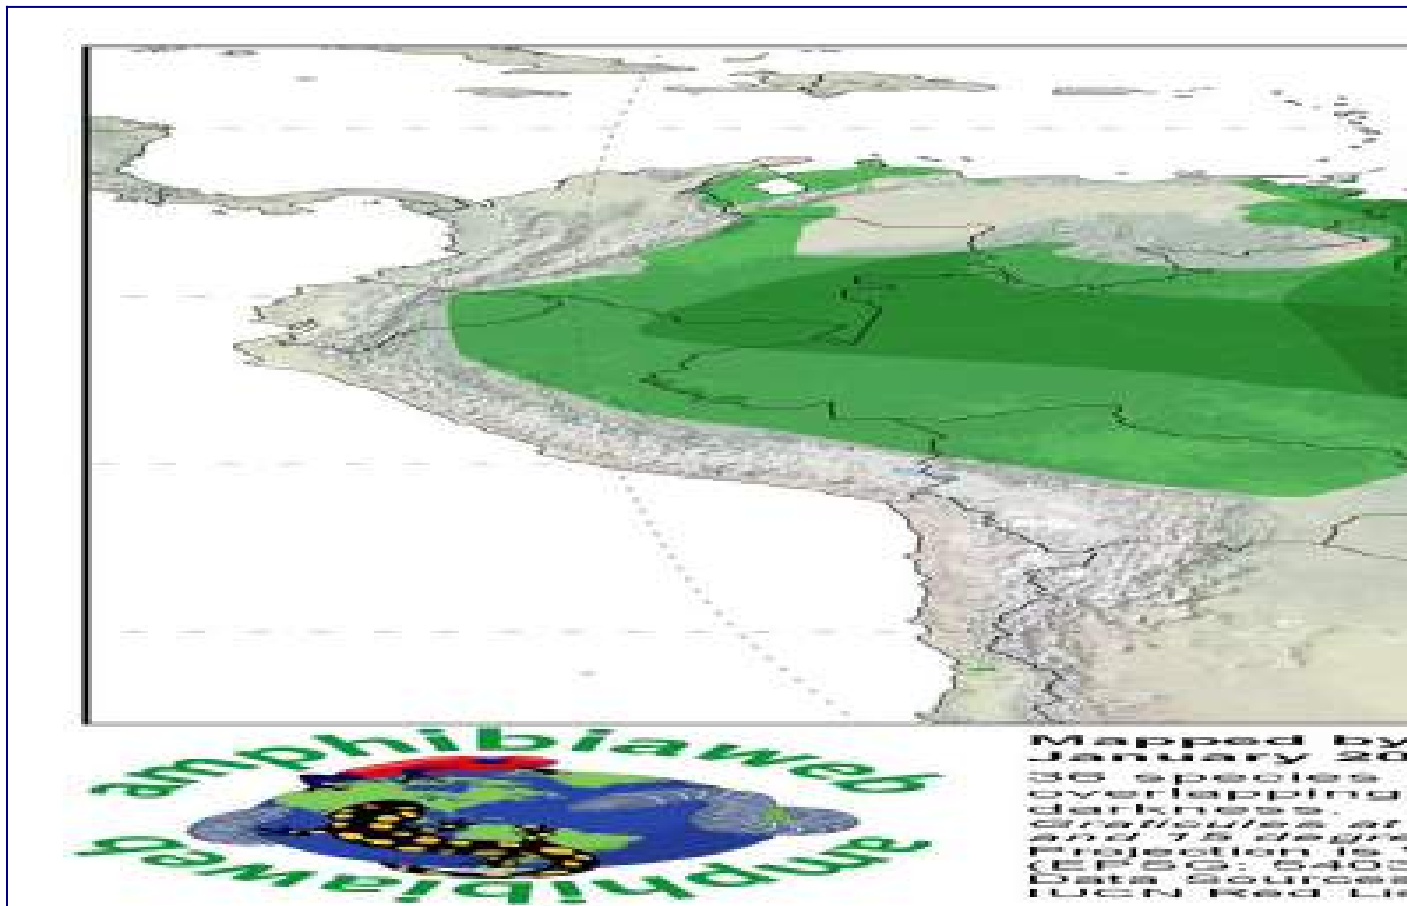

These frogs lack a tongue, have dorsoventrally flattened bodies, fully webbed hind feet, small dorsally placed the female's back. The fertilized eggs are later enveloped by skin and complete their development within the f

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Aquatic, living a variety of water bodies, such as lakes, ponds, and streams
- Males lack vocal cords and vocal sacs, but some are known to snap their hyoid apparatus and produce
- Tadpoles may be free-living and resemble small catfish due to their paired anterior barbells (*Xenopus*)
- Morphological characters include: 1) epipubis present; 2) unpaired epipubic muscle; 3) quadratojugal

- Distribution limited to parts of Africa and South America

# Ptychadenidae

67 species in 3 genera

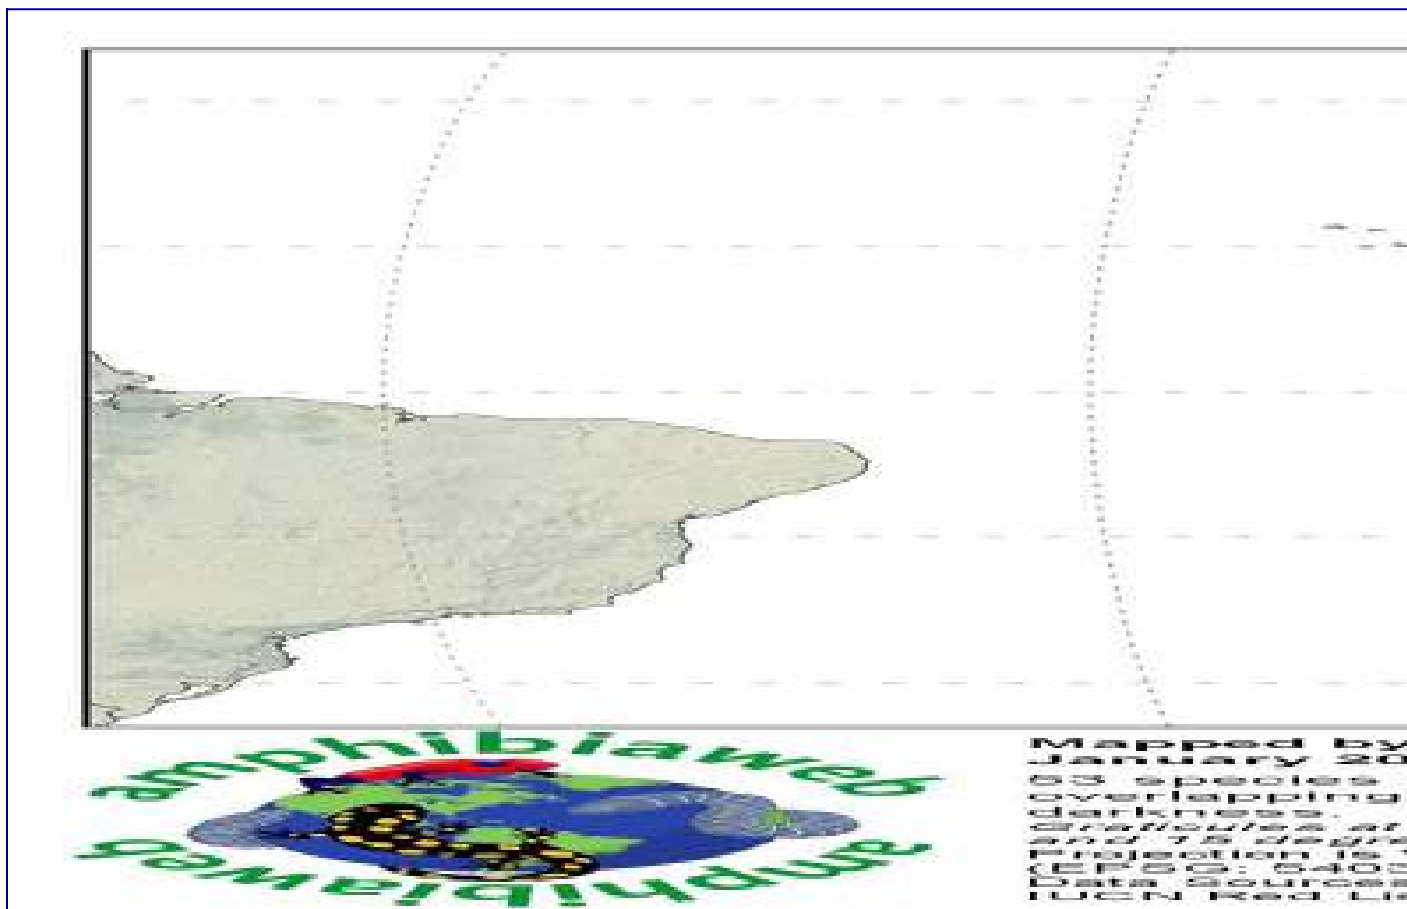

## ***Commonly Called Grassland Frogs, Ridged Frogs***

Members of this sub-Saharan African family was previously assigned to Ranidae until 2006 when they were moved to their own family. They are found in grasslands and savannas, lay eggs in temporary water bodies, which hatch into tadpoles. In general, these species are medium sized frogs with longitudinal ridges or stripes.

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Medium-sized frogs (40 - 60 mm snout-vent length), most with strong legs
- Habitat mainly savannah and grasslands with some species known from forests in lowland and montane areas
- Breeds in temporary water bodies, laying eggs that hatch into tadpoles
- Most species with longitudinal ridges or stripes
- Distribution limited to sub-Saharan Africa, except for *Ptychadena mascareniensis*, which has naturally spread to other regions

## Pyxicephalidae

91 species in 12 genera

## ***Commonly Called African Bullfrogs, Sand Frogs, Moss Frogs***

This family is organized into two subfamilies, Pyxicephalinae and Cacosterninae; the former are large, stocky

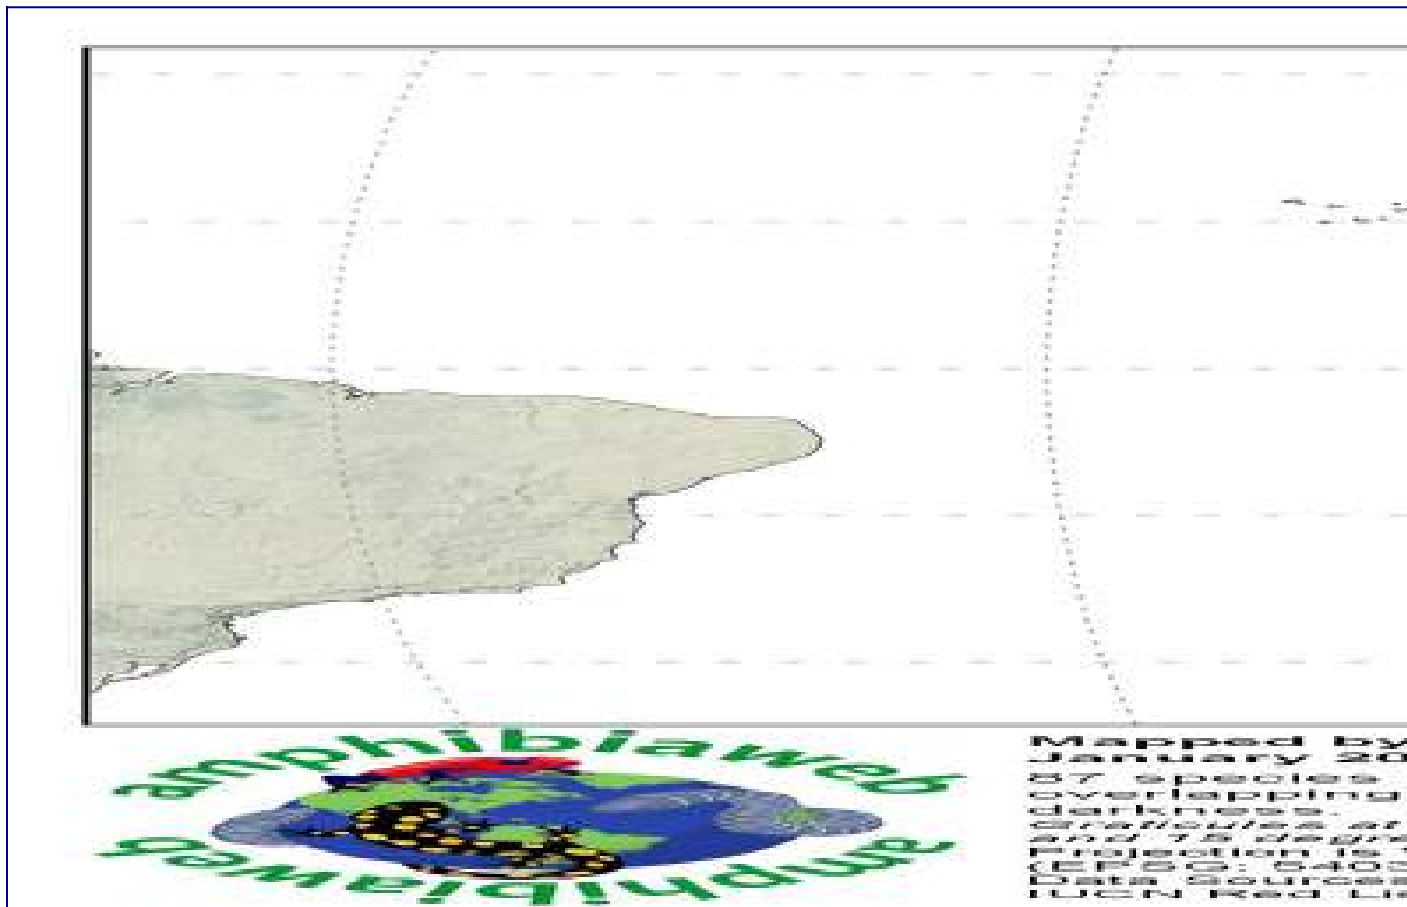

### **News Highlight:**

June 27, 2016: To gain a better understanding of the African genus *Amietia*, which is currently composed of 100 species, researchers from the University of Zimbabwe, a biodiversity hotspot, they found six undescribed species. All of the new species were found in unprotected areas.

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Occurs in a variety of habitats from savannah, grasslands, and scrub to rocky streams in forests
- Displays a variety of reproductive modes including laying eggs and free-living tadpoles to direct development
- Species may be terrestrial, semi-arboreal or semi-fossorial
- Many species are explosive breeders, appearing en masse after heavy rainfall
- Distribution throughout sub-Saharan Africa

## Ranidae

468 species in 25 genera

## ***Commonly Called True Frogs***

The Ranidae family includes species from around the world. They are well-known in North America where so Mark Twain's Celebrated Jumping Frog of Calaveras County was likely the ranid *Rana draytonii*).

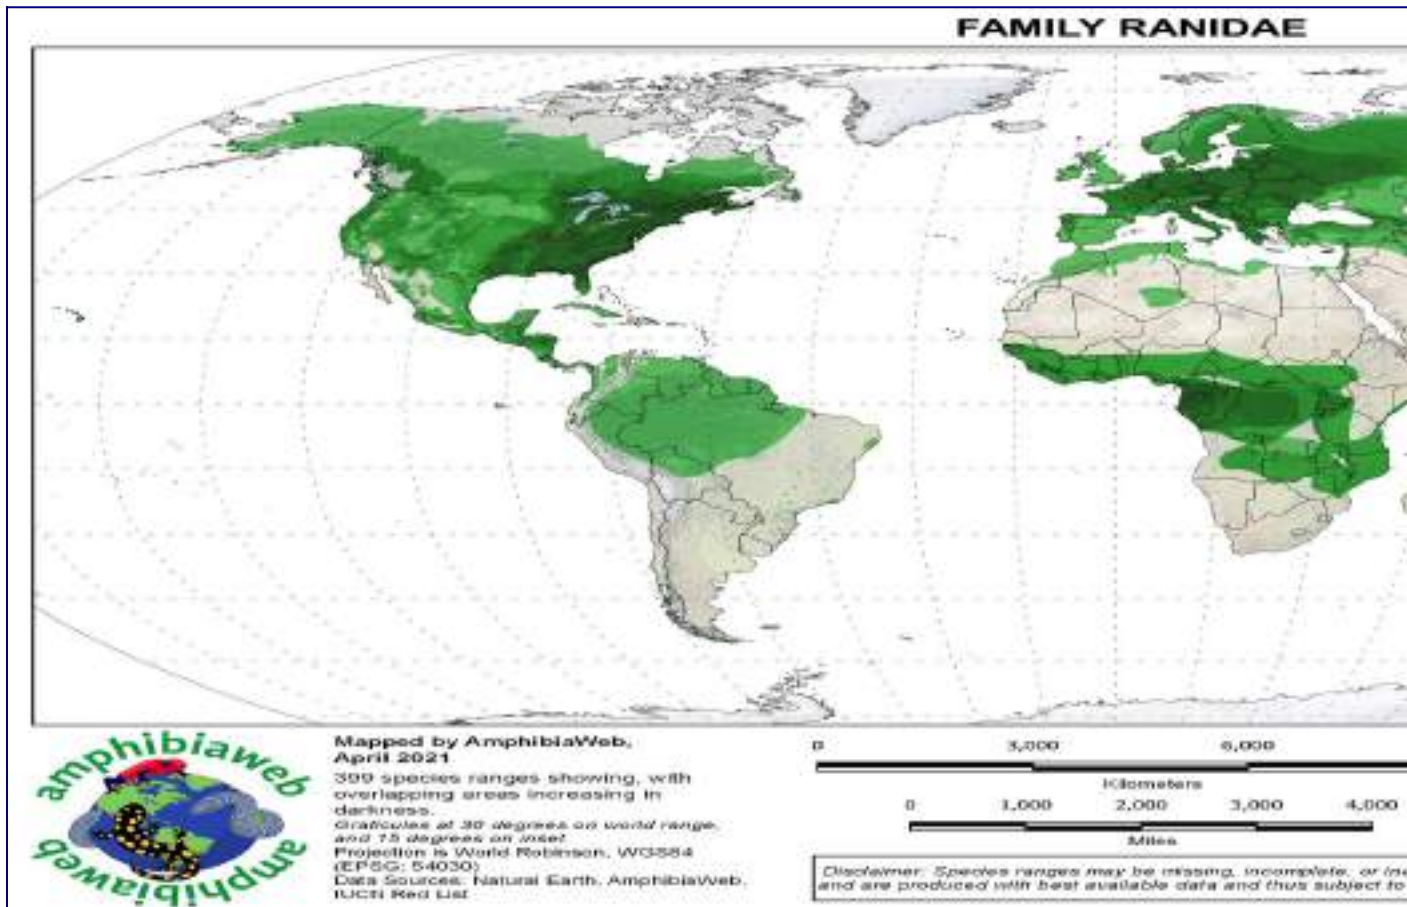

Ranids have generalized frog body forms with strong hindlimbs, toe webbing, and a generalized aquatic tadpole and breed in water to lay eggs that will hatch into free-living tadpoles.

Known as the True frogs, this family has undergone many taxonomic reorganizations and phylogenetic studies, but the relations of remaining species are still unresolved. Several genera were suggested by Frost et al 2006 for p show doing so would create problems of paraphyly in other genera. Instead they recognized subgenera within *Lithobates* as the subgenus for the *Rana palmipes* group. AmphibiaWeb recommends the optional use of these written as *Rana (Aquarana) catesbeiana*, for example.

Written by AmphibiaWeb

## **Notable Family Characteristics**

- Terrestrial and aquatic
- Inhabits a wide range of habitats, ecoregions and elevations
- Eggs are typically laid in water and hatch into free-living tadpoles
- Morphological features include: smooth moist skin, strong hindlimbs, webbed toes, usually a distinct v
- Distributed worldwide except for southern South America, Madagascar, and most of Australia.

## Ranixalidae

19 species in 2 genera

### ***Commonly Called* Indian Frogs, Leaping Frogs**

This ancient family is endemic to central and southern India, especially in the biodiversity hotspot of the Western Ghats. In recent years (2010's) and some authors believe there is more cryptic diversity to be discovered.

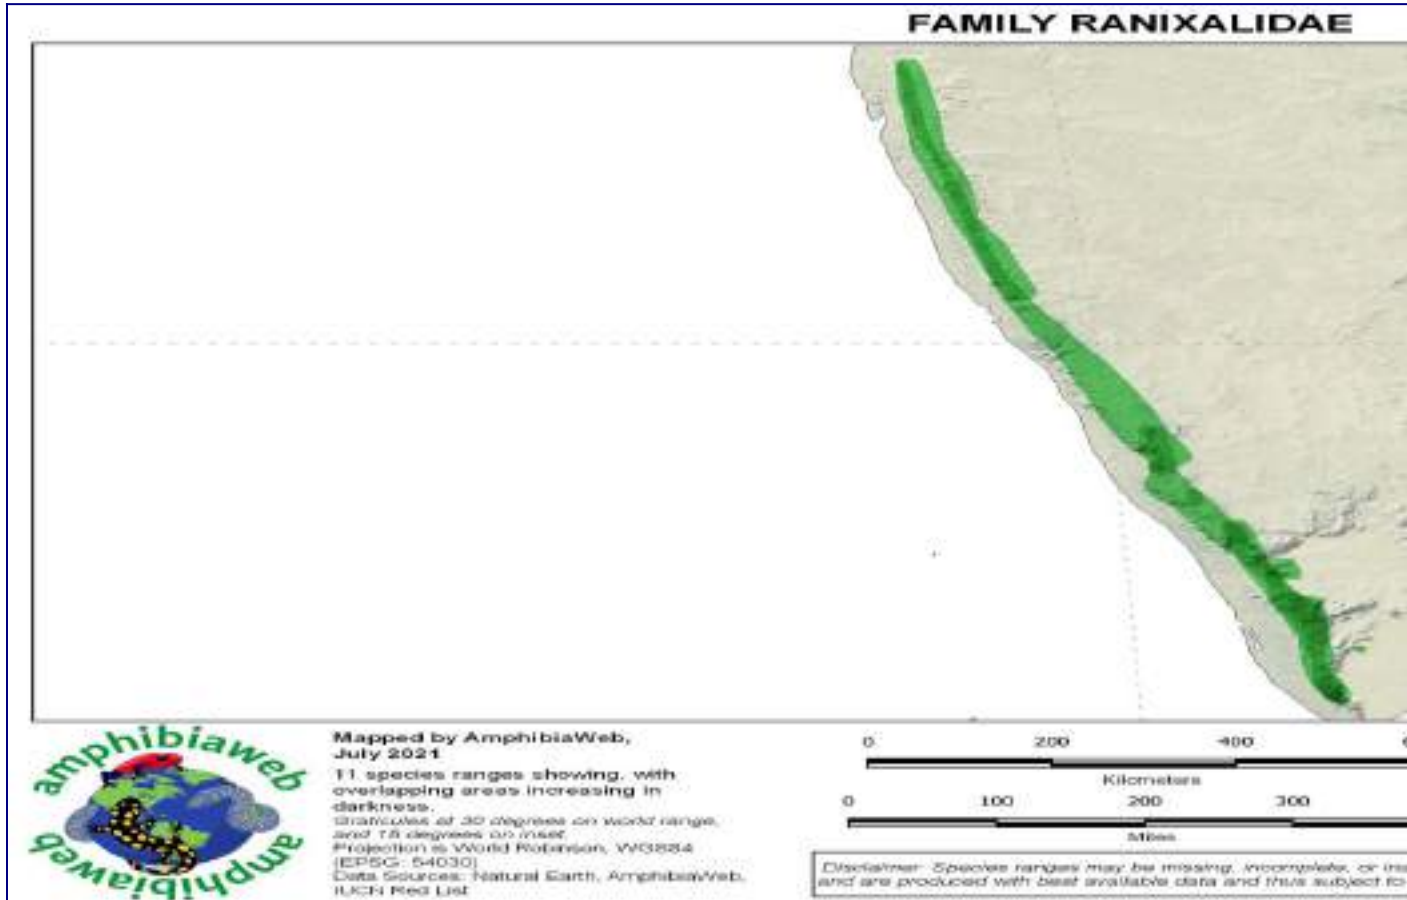

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Occurs terrestrially in leaf litter or streams in tropical forests
- Morphological characters include: oval pupils, median lingual tubercle, distinct tympanum of varying

supratympanic fold, partial dorsal skin folds or prominent skin warts present, and Y-shaped terminal p distinct dorsoterminal grooves

- Females tend to be larger than males; males have femoral glands and spicules on the margins of the jaw
- Many species appear most active at night
- Distribution limited to central and southern India, especially in the Western Ghats

## Rhacophoridae

464 species in 22 genera

### *Commonly Called Asian Tree Frogs, Gliding Frogs*

Asian tree frogs are most closely related to true frogs (Ranidae) but seem to be the ecological equivalents of them. They have specialized adaptations at the ends of the fingers to aid in climbing. Most Asian tree frogs have large eyes with horizontal pupils and black and white. Many have flash coloration (bright, patterned colors) on the inner thighs or axillary, which can be used to startle predators. Some members of the genus *Rhacophorus* are able to glide by extending their limbs out as they jump, thus serving to increase their surface area (this gliding is called "parachuting").

Rhacophoridae was previously considered a subfamily of Ranidae, but several studies agree on its monophyly.

Rhacophorinae, the former with one genus, *Buergeria*, limited to east Pacific islands of Taiwan and Japan.

This family includes several extinct species from Sri Lanka, including: [\*Pseudophilautus adspersus\*](#), [\*Pseudophilautus extirpo\*](#), [\*Pseudophilautus halyi\*](#), [\*Pseudophilautus leucorhinus\*](#) (now referred to as *wynaadensis*), [\*Pseudophilautus nasutus\*](#), [\*Pseudophilautus oxyrhynchus\*](#), [\*Pseudophilautus pardus\*](#), [\*Pseudophilautus rugatus\*](#), [\*Pseudophilautus zal\*](#), [\*Pseudophilautus zimmeri\*](#). Many of these extinct species are only known from one or a few specimens; [\*Pseudophilautus hypomelas\*](#) and [\*Pseudophilautus stellatus\*](#) were considered extinct for over a century until their rediscovery.

### News Highlight

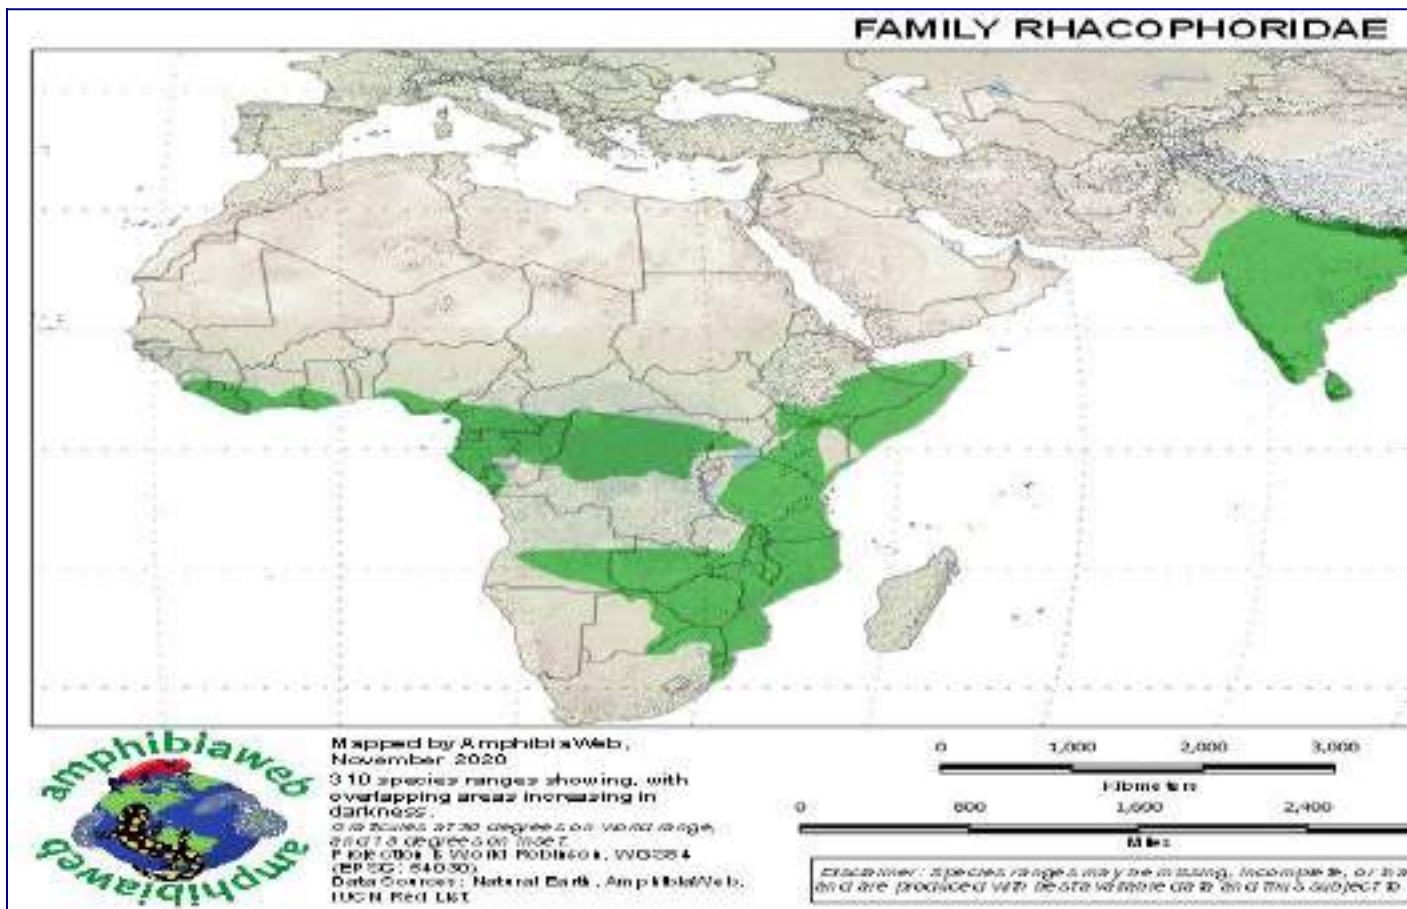

August 31, 2015: The large (over 400 species) family Rhacophoridae, widespread in the Asian subtropics, exhibits an extraordinary array of life history modes. A multigene phylogenetic analysis of all major clades and nearly a third of the family was published in [2015](#) to conclude that the ancestral mode was fully aquatic eggs and larvae. The ancestral forms of all but a few genera are thought to have been of having been terrestrial gel nesters. Direct development and foam nesting characterize the vast majority of the family, occurring twice within the family. As a probable consequence of these evolutionary events, rhacophorids thrive in a wide range of habitats.

August 29, 2016: Factors responsible for the high species richness of tropical amphibians remain elusive. In a new study, *Raorchestes*, the largest vertebrate radiation in Peninsular India, tests alternative hypotheses using a well-resolved phylogeny and geographic events, glaciation and climatic history, and ecology (e.g., ecological gradients). All of the factors tested vary across space in their effects and have acted at different times during the last (at least) 30 million years. The Palghat Gap (Palghat Gap) in the Western Ghats system, and the importance of the geography of the different massifs. The formation has been allopatric in nature, high elevation massifs have acted as centers of diversification, and the high elevation portions of the southern Western Ghats act as biodiversity "museums". (DW)

Written by AmphibiaWeb

### Notable Family Characteristics

- Arboreal but *Buergeria* species may be more terrestrial
- Highly variable reproductive modes, from aquatic tadpoles, foam or cavity nest builders to direct development
- Axillary amplexus
- Some morphological characters include: 1) paired palatines and frontoparietals in skull; 2) cartilaginous structures between the terminal and penultimate phalanges; 3) toe discs
- Distribution from sub-Saharan Africa, Madagascar to South Asia, including Taiwan and Japan

## Rhinodermatidae

3 species in 2 genera

### ***Commonly Called Mouth-brooding Frogs, Darwin's Frogs***

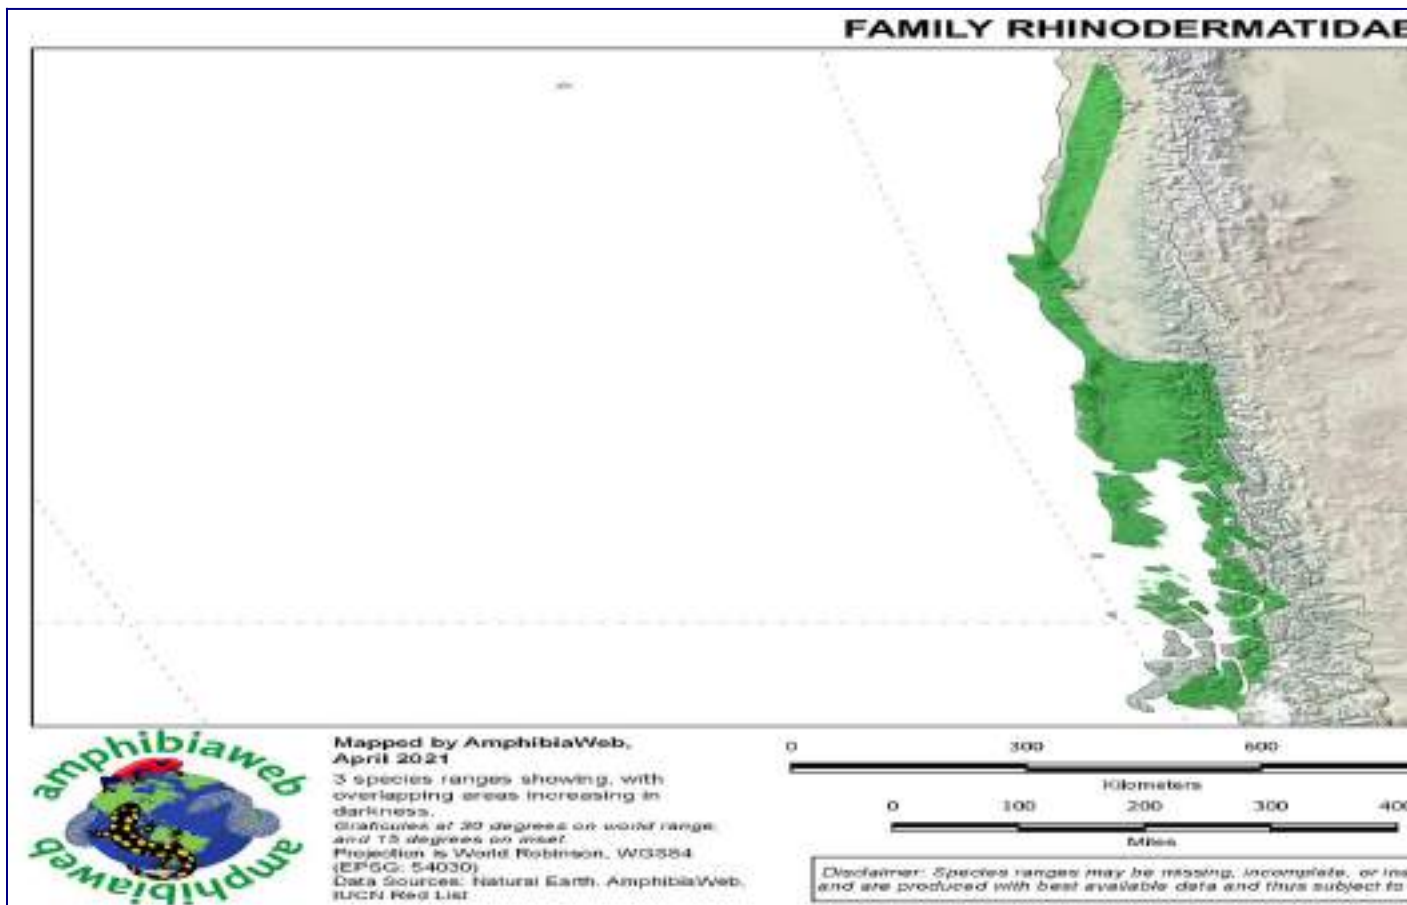

Members of this family would be included within the Cycloramphidae if it were not for their strange modes of reproduction. In some species, the tadpoles are carried to water in the mouth of the male (*Rhinoderma rufum*) or complete their development within the mouth of the male. In *Rhinoderma darwinii*, the larvae receive nutrition from viscous secretions within the male's vocal pouch, rather than from the male's mouth. The etymology of their generic and familial name means "rhinoceros-nosed" referring to the large, bumpy snout.

All members of this family are listed by IUCN as Vulnerable or Critically Endangered.

Written by AmphibiaWeb

## Notable Family Characteristics

- Terrestrial
- Occurs in temperate wet forests and riparian corridors
- Proboscis-like extension at the tip of the snout is present lending its family and generic name *Rhinoderma*
- Egg-layers with parental care, including the extreme form of brooding and feeding within the vocal sac of *darwini*
- Distribution limited to southwestern Argentina and Chile in South America

## Rhinophrynidae

1 species in 1 genus

### Commonly Called Burrowing Toads

*Rhinophrynus dorsalis*

Photo by Paddy

[\(Click for family page\)](#)

The only living representative of this family is *Rhinophrynus dorsalis*. Also known as the Mexican Burrowing Toad, this species has multiple specializations for its burrowing lifestyle such as a pointed snout for digging into the ground, short and strong arms and legs, and a pectoral girdle that overlaps the back of the head. The pointed snout, globose body, and small eyes give it a teardrop appearance. These frogs are specialized for eating ants, and do so with a specialized, ant-like tongue that is protruded through a narrow opening at the front of the mouth, unlike most frogs which open their mouth and project a tongue. They also lack teeth. They spend most of their lives underground and only come to the surface during the rainy season.

Its closest sister group is Pipidae. In both families, tadpoles lack beaks and denticles and possess paired spiracles (unlike most tadpoles).

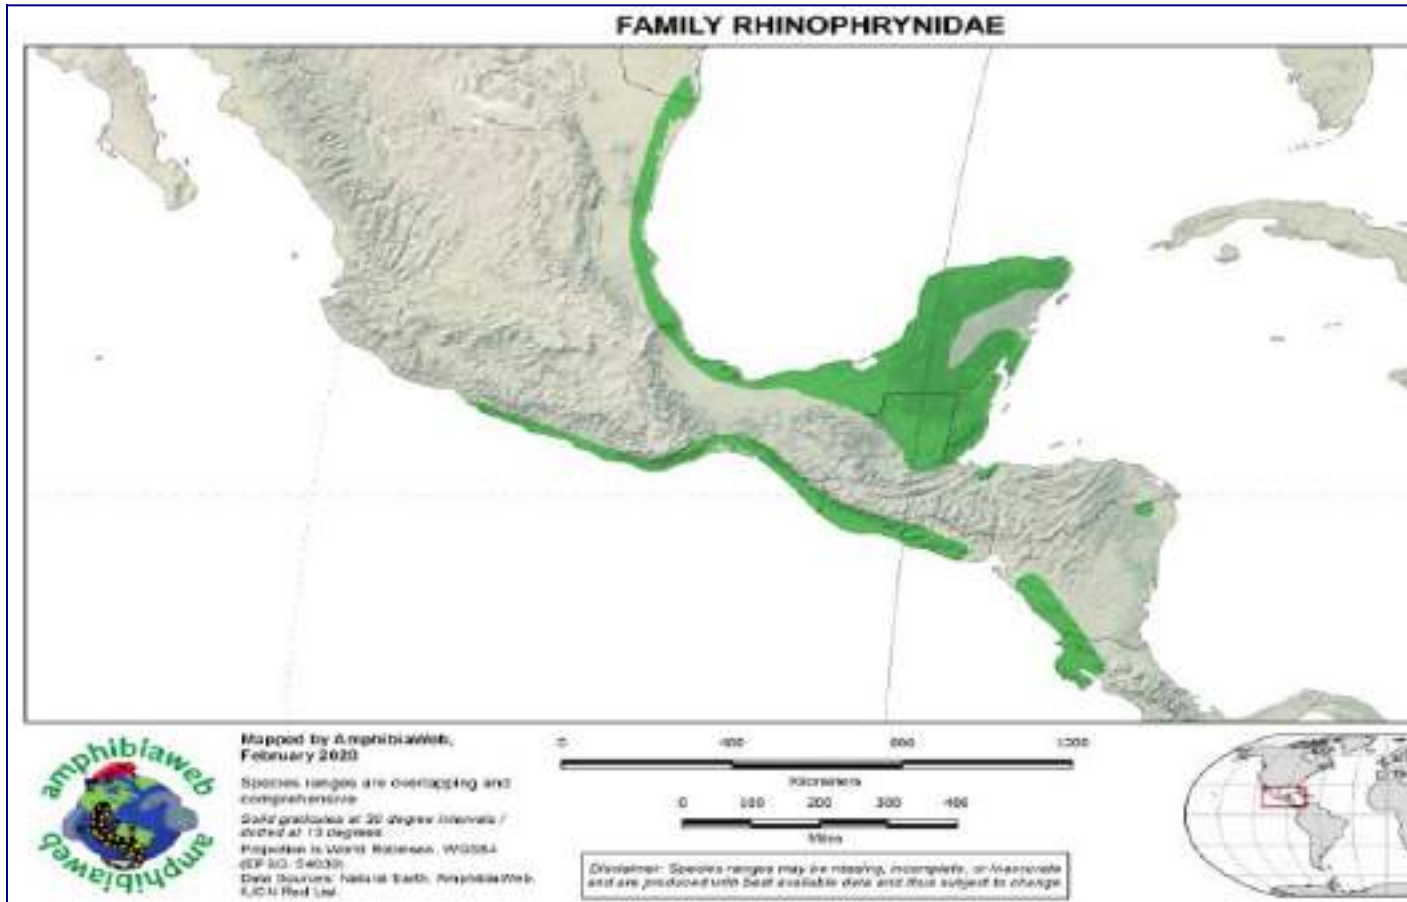

Written by AmphibiaWeb

### Notable Family Characteristics

- Fossorial
- Habitat typically arid or savanna, tropical or subtropical, non-forested areas with friable soil
- Small head with small eyes, nostrils oriented towards top of head, and

pointed snout

- Some morphological characters include: long tongue specialized for feeding on ants; keratinized tubercles on metatarsus used in digging; pectoral girdle that overlaps the back of the head
- Feeds on ants and termites
- Eggs laid in ephemeral water after heavy rains and breeding, which hatch into tadpoles (Type I)
- Distribution limited to Central America, mainly along the coasts of Mexico, Nicaragua and Costa Rica.

## Scaphiopodidae

7 species in 2 genera

### Commonly Called Spadefoot Toads

*Scaphiopus couchii*

Photo by David B. Wake

[\(Click for family gallery\)](#)

This group was formerly part of the family Pelobatidae. Scaphiopodids plus Pelobatids are collectively known as the Spadefoot Toads, owing to a keratinized digging spade present on each hindfoot. These medium-sized ( - 80 mm snout-vent length) toads are desert dwellers, spending considerable time underground each year until the rains arrive. At that point they rapidly move to the surface and breed explosively in temporary pools. Tadpole development is extraordinarily rapid in this group.

#### News Highlight:

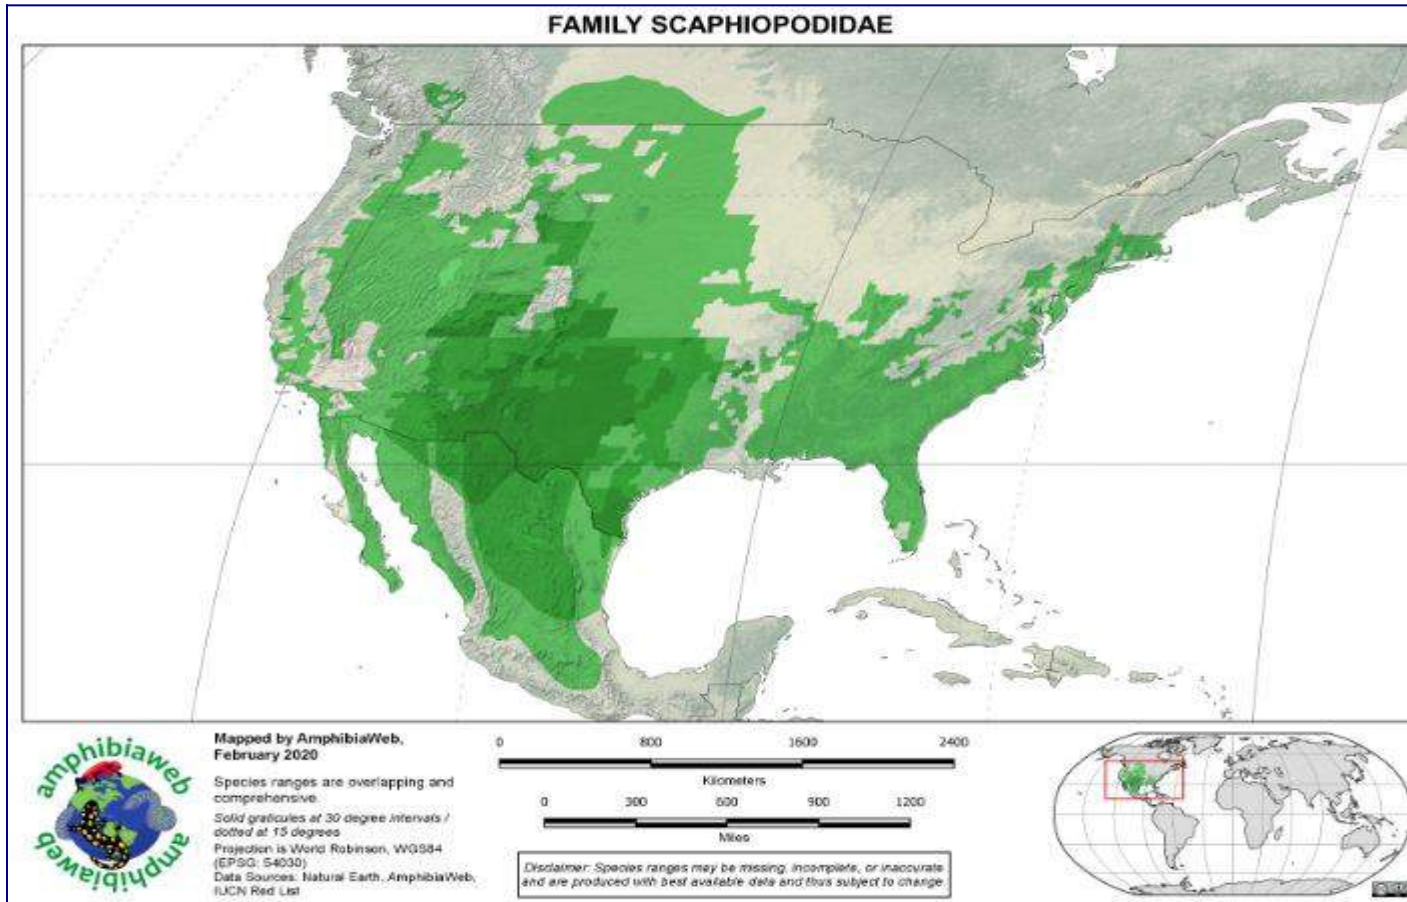

November 6, 2017: Spadefoot toads (Scaphiopodidae, Pelobatidae) are noteworthy for their divergent larval periods and responsiveness to pond drying. A study by [Kulkarnie et al. \(2017\)](#) compared hormonal variation underlying these differences. In response to pond drying, *Pelobates cultripes* and *Spea multiplicata* accelerate metamorphosis, increase standard metabolic rate (SMR), and elevate whole-body content of thyroid hormone and corticosterone. In contrast, *Scaphiopus couchii*, with the shortest larval period, highest whole-body thyroid hormone and corticosterone content, and highest SMR, is least affected. Their findings support the hypothesis that the atypically rapid and canalized development of *S. couchii* evolved by genetic accommodation of endocrine pathways which control metamorphosis, thus showing how phenotypic plasticity within species can evolve into trait variation among species. (DW)

Written by AmphibiaWeb

### Notable Family Characteristics

- Fossorial, except to breed
- Inhabits deserts and other arid regions
- Breeding is highly seasonal, and large numbers surface with rains to breed and lay eggs in temporary water bodies
- Morphological features include a keratinous, spadelike metatarsal tubercle with a well-ossified prehallux, used to burrowing and digging
- Distributed widely in North America

Cartography Credit: Zoe Yoo, UC Berkeley

Range maps sources: AmphibiaWeb, UC Berkeley, and IUCN RedList

## Sooglossidae

4 species in 2 genera

### Commonly Called Seychelles Frogs

This family of small frogs is comprised of two genera, *Sechellophryne* and *Sooglossus*. Members of this family are found only in the Seychelles and most closely related to the family Nasikabatrachidae, making them a primitive group of Neobatrachia to display inguinal amplexus (a primitive form of amplexus). Sooglossids are secretive frogs that are active on the surface except during rains. Each species has a distinctive call. Females of *Sooglossus sechellensis* and larval development occur in this family. Sooglossids possess tarsal sesamoid bones.

Written by AmphibiaWeb

### Notable Family Characteristics

- Terrestrial but found under cover of leaf litter or rocky crevices
- Inguinal amplexus
- Direct development (*Sechellophryne*) and endotrophic tadpoles which develop on the backs of parents
- Some of the smallest species of frogs, 10-40 mm snout-vent length
- Morphological features include: tarsal sesamoid bones
- Distribution limited to Seychelles Islands, off the coast of Africa

Cartography Credit: Zoe Yoo, UC Berkeley

## Strabomantidae

833 species in 20 genera

### ***Commonly Called* Cloud Forest Landfrogs, Landfrogs, Terrestrial-breeding Frogs**

This is one of the most speciose families as defined by S. B. Hedges, W. E. Duellman, and M. P. Heinike (2008) as cloud forest breeding frogs. In 2011, Pyron & Wiens (2011) proposed that Strabomantidae is nonmonophyletic and considered it a subfamily of Craugastoridae (a family also proposed by Hedges et al. 2008). However, Blackburn and Wake (2011) reviewed the delimitation proposed by Hedges et al. (2008). Thus, Strabomantidae and Craugastoridae are considered separate families.

What little is known of the biology of this family suggests they do not have larval forms and instead are direct-developing and hatch as miniature froglets.

#### **News Highlight:**

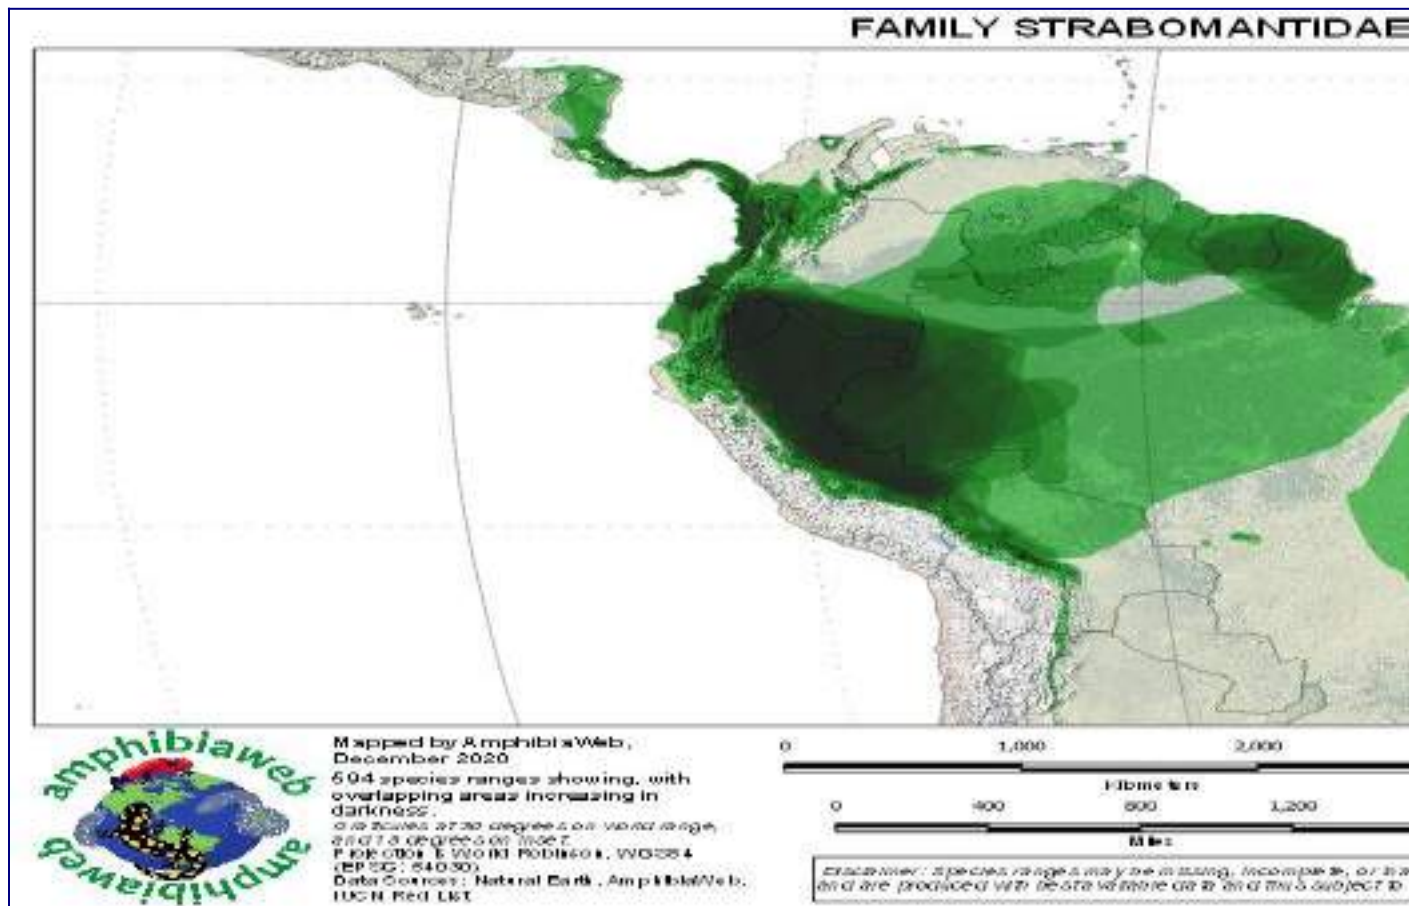

January 9, 2023: An important life history trait is body size, which can be affected by environmental and evolutionary relationships in the speciose, neotropical genus *Pristimantis*, which has a distribution across wide latitudes. A study of 584 known *Pristimantis*, phylogenetic information from 257 species, and information on their environment found that body size and sexual size dimorphism were correlated with climatic variation associated with heat balance (temperature) and resource availability (elevation). Additionally, despite the majority of species displaying sexual size dimorphism, males are larger than females. This correlation may be the result of fecundity selection, reproductive energy requirements, or other factors. Evidence that they are experiencing different selective pressures, the rate of body size evolution appears to vary. This study provides a case for bioclimatic factors in body size evolution, it is a good launching point to generate hypotheses about the evolution of body size in this genus.

sexual size dimorphism. (AChang)

Written by AmphibiaWeb

### Notable Family Characteristics

- Primarily small bodied frogs
- Terrestrial breeding
- Direct development
- Mostly terrestrial species but some arboreal species are present
- Distribution in South America

## Telmatobiidae

63 species in 1 genus

### Commonly Called Water Frogs

*Telmatobius ventriflavus*

Photo by Alessandro Caterino

[\(Click for family gallery\)](#)

Formerly a subfamily of Ceratophryidae, molecular evidence supports a monotypic family of medium to large, flattened frogs. Many of the species have loose skin, which hangs in folds, especially in the aquatic species and provides a greater surface area for cutaneous respiration. The Lake Titicaca Frog, *Telmatobius culeus*, is well known for its prominent skin folds and is completely aquatic.

Written by AmphibiaWeb

### Notable Family Characteristics

- Medium to large snout-vent length, up to 140 mm
- Many species are aquatic, some semi-terrestrial
- Morphological characters include: flattened head; non-coossified skin on skull; recurved fang-like teeth on maxilla, premaxilla and vomer; cartilaginous sternum; knobbed terminal phalanges
- Axillary amplexus

- Distribution limited to South America, mainly the Andean region

Salamanders

## Ambystomatidae

32 species in 1 genus

### Commonly Called Mole Salamanders

A family of mostly large robust salamanders (up to 340 mm in *Ambystoma tigrinum*), Mole salamanders are v

to Mexico City. These species occur in a variety of habitat, requiring aquatic habitat for their larval stage. This is an obligate paedomorphic (maintaining juvenile traits as adults) species, such as the famous Axolotl (*Ambystoma mexicanum*). This species can be induced to metamorphose by the addition of iodine into their habitat. Polyploidy and gynogenetic lineages in this family spend most of the year underground in rodent burrows and emerge only on rainy nights to mate and lay eggs. Large numbers of individuals migrate to mating ponds.

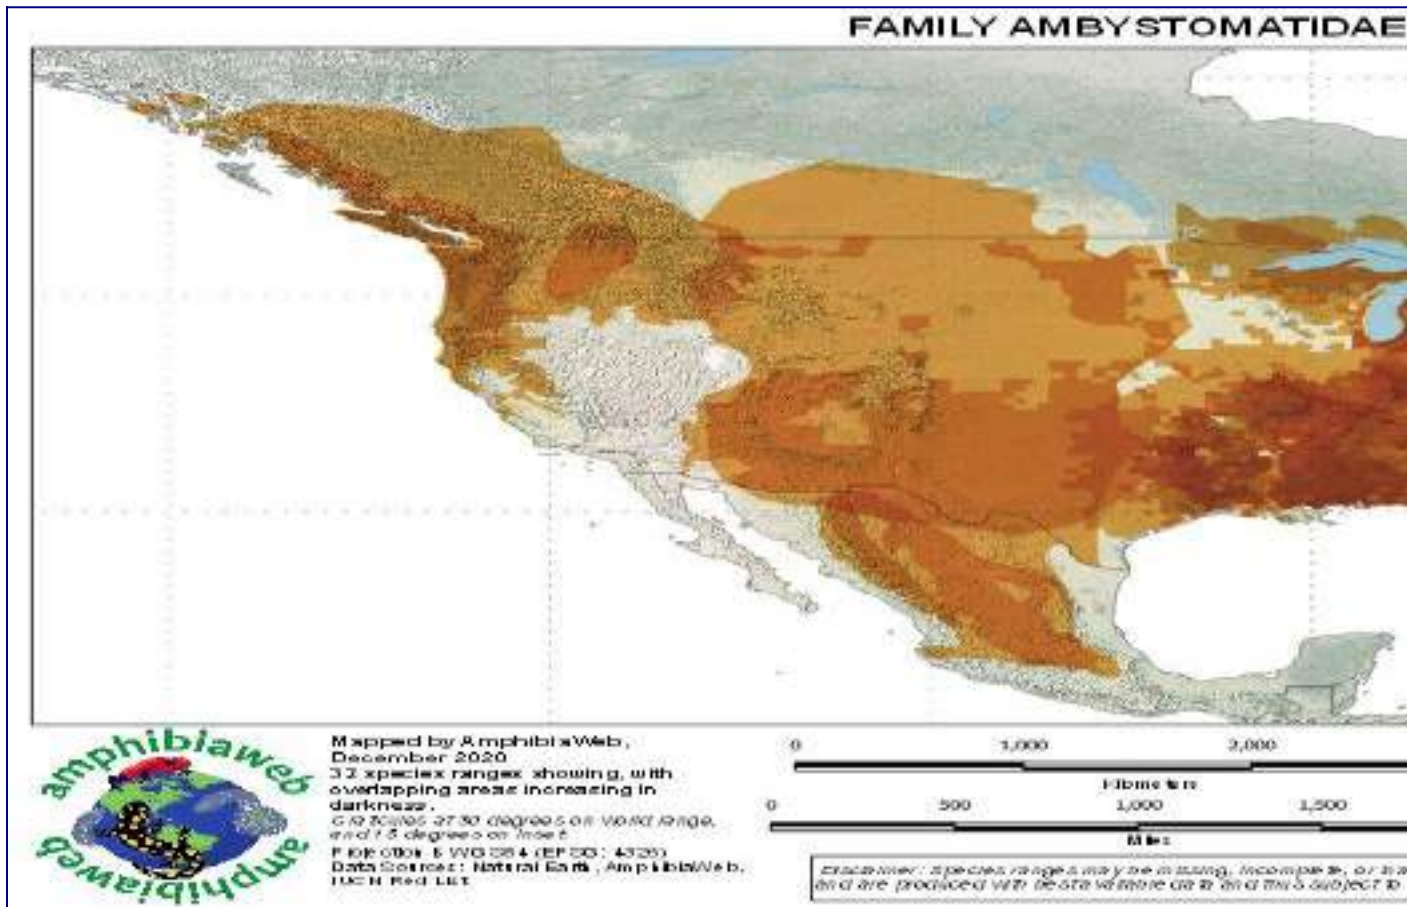

### News Highlight

October 3, 2016: Asexual, parthenogenetic animals are rare, and although they have a short-term selective advantage that should not persist in the long-term. Despite this theory, an asexual lineage of mole salamanders (*Ambystoma talpoideum*) has persisted for millions of years. Cryptic sex has been proposed as an explanation for why this lineage has persisted. [Gibbs et al. \(2016\)](#) used specific microsatellite DNA markers to compare gene flow to asexual females from either sympatric or allopatric populations. Their results suggest that unidirectional gene flow was occurring from sympatric sexual males to asexual females. Their results suggest a selective advantage that prevents the partial genome exchange from sexual males from overwhelming the lineage.

Written by AmphibiaWeb

### Notable Family Characteristics

- Medium to large salamanders
- Some morphological characters include: 1) lacrimal bone absent; 2) exoccipitals, prootics, and opisthotics; 3) teeth may be in a transverse orientation in the mouth; 4) costal grooves; 5) well-developed lungs.
- Adults typically live in burrows or talus slopes underground and return to waterbodies or slow streams to breed.
- Includes species which retain juvenile morphology as sexually mature adults, and thus are permanently juvenile (paedomorphic)
- Includes species which exhibit triploidy and gynogenesis (*Ambystoma platineum* and *A. tremblayi*, respectively)
- Internal fertilization
- Distributed widely in North America

## Amphiumidae

3 species in 1 genus

## ***Commonly Called Amphiumas***

Amphiumas are large, aquatic, eel-like salamanders (up to 1 m), with 4 highly reduced limbs, native to eastern North America but hatch as short-lived aquatic larvae. Tail is laterally compressed and makes up one third of the total body length. Features of no eyelids or tongue, open spiracle, a lateral line system, and four internal gill arches which aid the respiration. When the body of water goes dry, they are able to bury themselves in the mud and form a mucous cocoon that keeps them alive until they emerge. They can go up to three years without food and have been known to live up to 27 years.

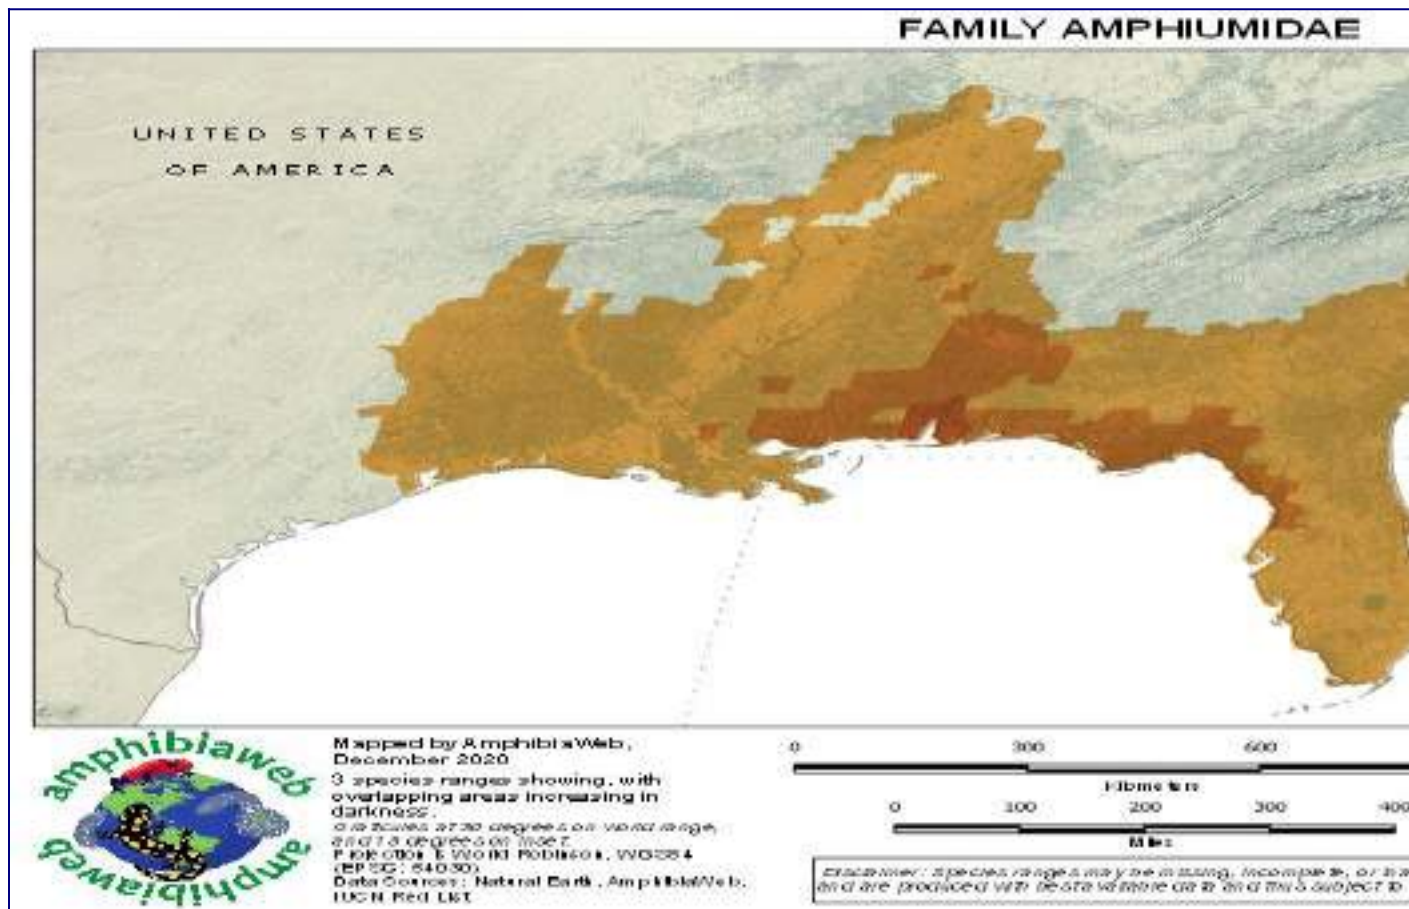

Its sister group is likely the Plethodontidae.

Written by AmphibiaWeb

## **Notable Family Characteristics**

- Large, aquatic salamanders
- Paedomorphic
- Highly reduced limbs which nonetheless bear digits, varying from 1 (*A. pholeter*) to 3 (*A. tridactylum*)
- Other morphological characters of the adults include: 1) premaxillae fused; 2) pterygoid reduced; 3) limb girdles reduced (3, 2, or 1 toe per foot, which is a species-specific character); 4) has lungs; 5) costal grooves.
- Internal fertilization
- Eggs are laid on land before hatching as aquatic larvae
- Females guard nests
- Distribution limited to southeastern North America

# Cryptobranchidae

7 species in 2 genera

***Commonly Called Giant Salamanders, Hellbender***

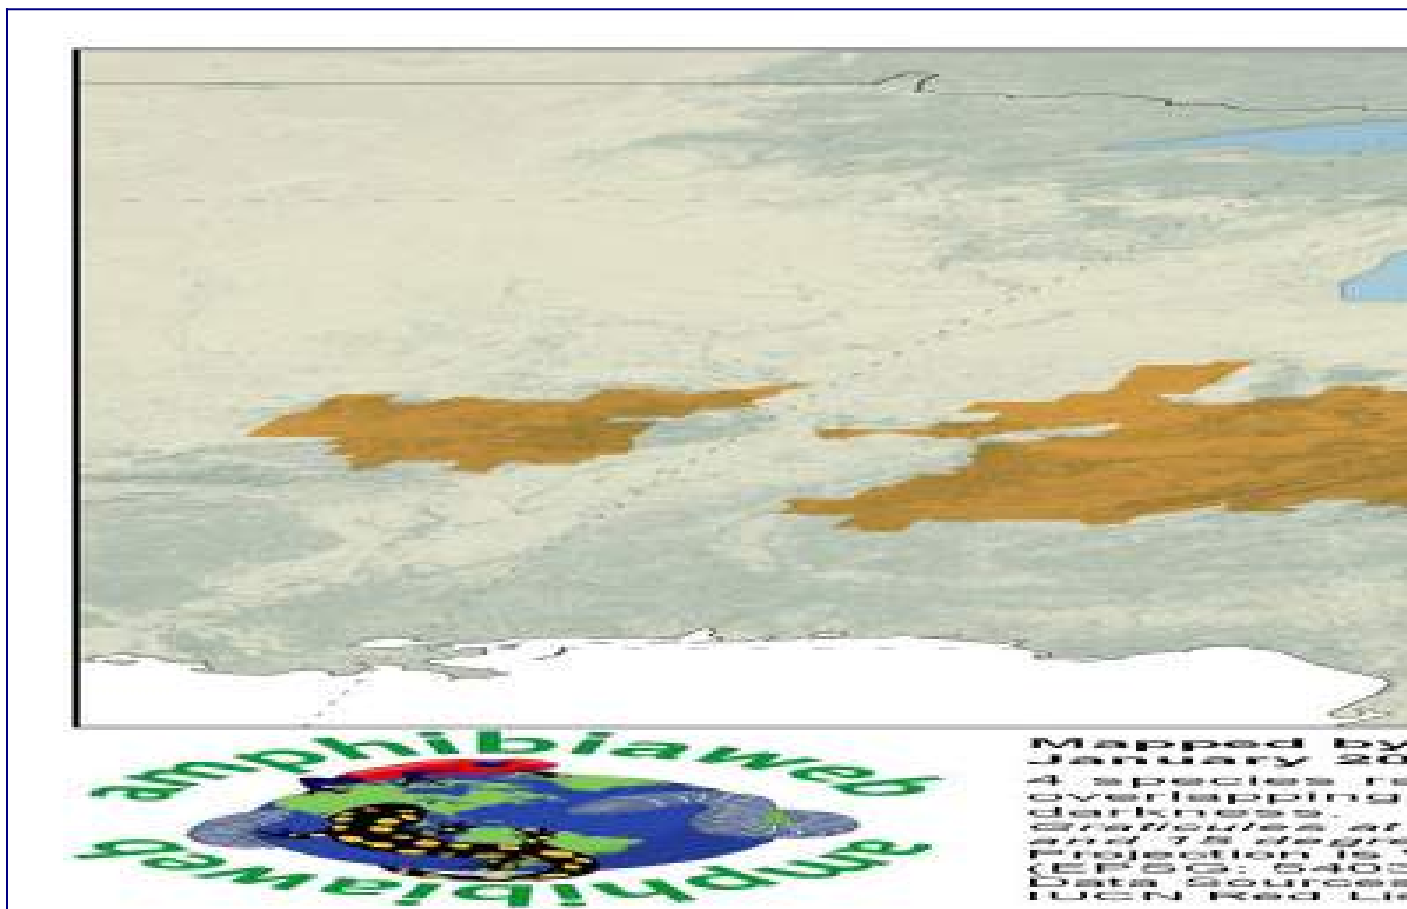

This family is named after one of their paedomorphic features, gill slits (from the Greek words *kryptos*=hidden). They are specialized suction feeders that consume crustaceans, lampreys, fish, frogs, reptiles, and small mammals. Cryptobranchids are specialized suction feeders.

Its closest sister group is Hynobiidae.

Written by AmphibiaWeb

## Notable Family Characteristics

- Inhabits clear streams and rivers with rocky substrates
- Some morphological characters include: 1) ribs uncapitate; 2) operculum fused to the ear capsule (also fused to the skull)
- Nocturnal
- Carnivorous suction feeders
- External fertilization
- Distribution of the species include select montane regions in China, Japan, and southeastern United States

# Dicamptodontidae

4 species in 1 genus

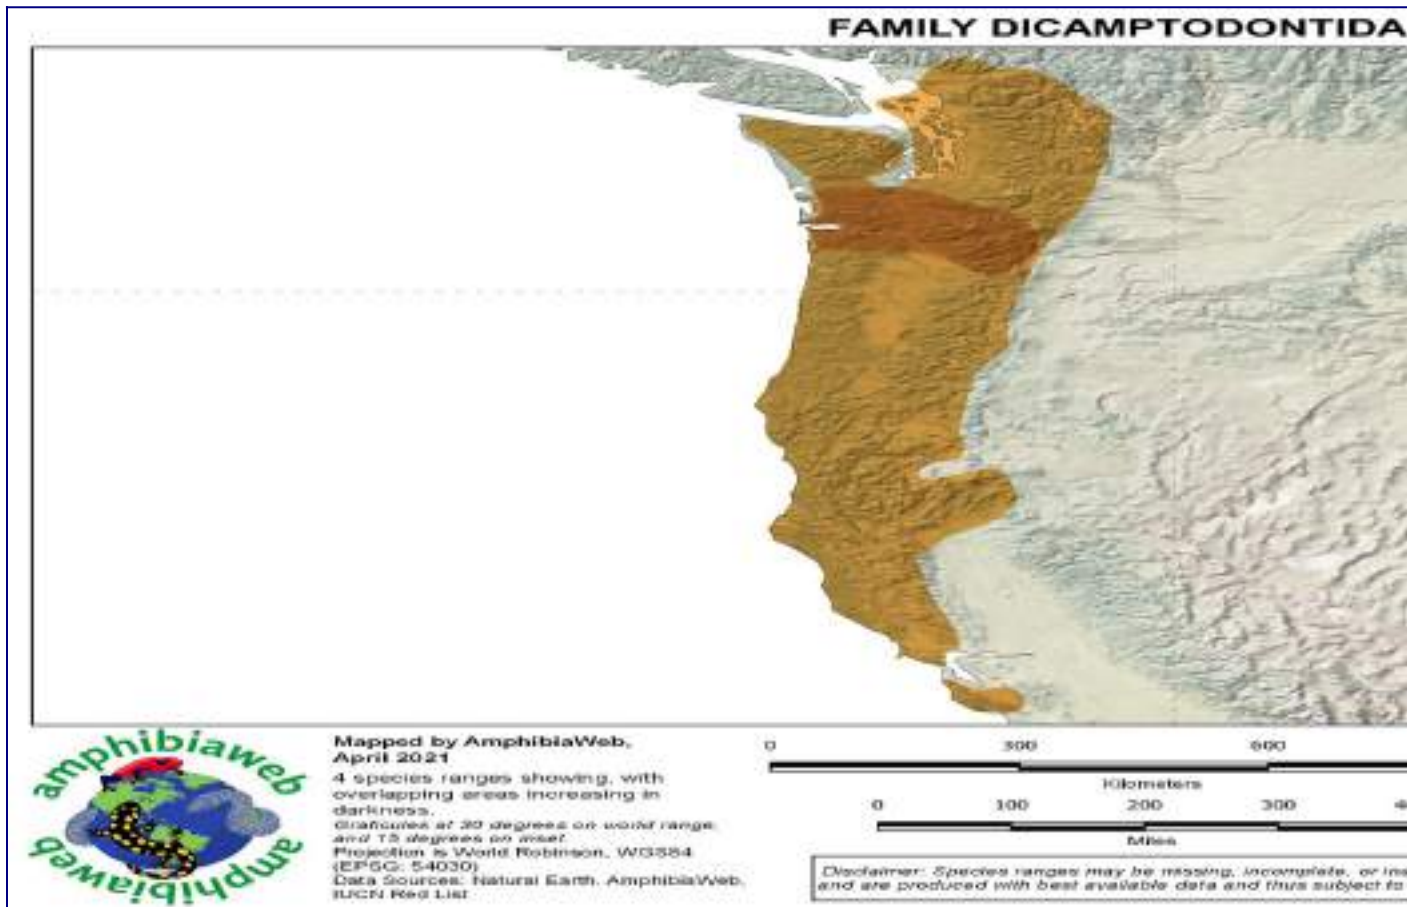

## *Commonly Called Giant Salamanders*

Medium to large terrestrial salamanders, known from the western United States. Largest living terrestrial salamanders. Larvae require 2 to 4.5 years to reach metamorphosis. Members of this family are restricted to wooded areas throughout the Pacific Northwest. They tend to be nocturnal, they can also be found in dark, heavy canopied forest (usually redwood forests). Individuals can be aggressive and may cause you to bleed if bitten. They are also known to eat small mammals.

Written by AmphibiaWeb

## Notable Family Characteristics

- Inhabits moist forests in the Pacific Northwest
- Some morphological characters are: 1) vomerine teeth in "M" shape; 2) lacrimal present; 3) marbled dorsal pattern
- Terrestrial
- Eggs hatch into aquatic larvae which can live in perennial streams up to 4 or more years before metamorphosing
- Distribution limited to the Pacific Northwest and the San Francisco Bay Area of western North America

# Hynobiidae

98 species in 9 genera

## ***Commonly Called Asian Salamanders***

Small to medium size (with *Ranodon* reaching up to 200 mm) terrestrial or aquatic salamanders that are distributed in Asia. Most species have external fertilization and aquatic larvae. Hynobiids are the sister taxon of the Cryptobranchidae,

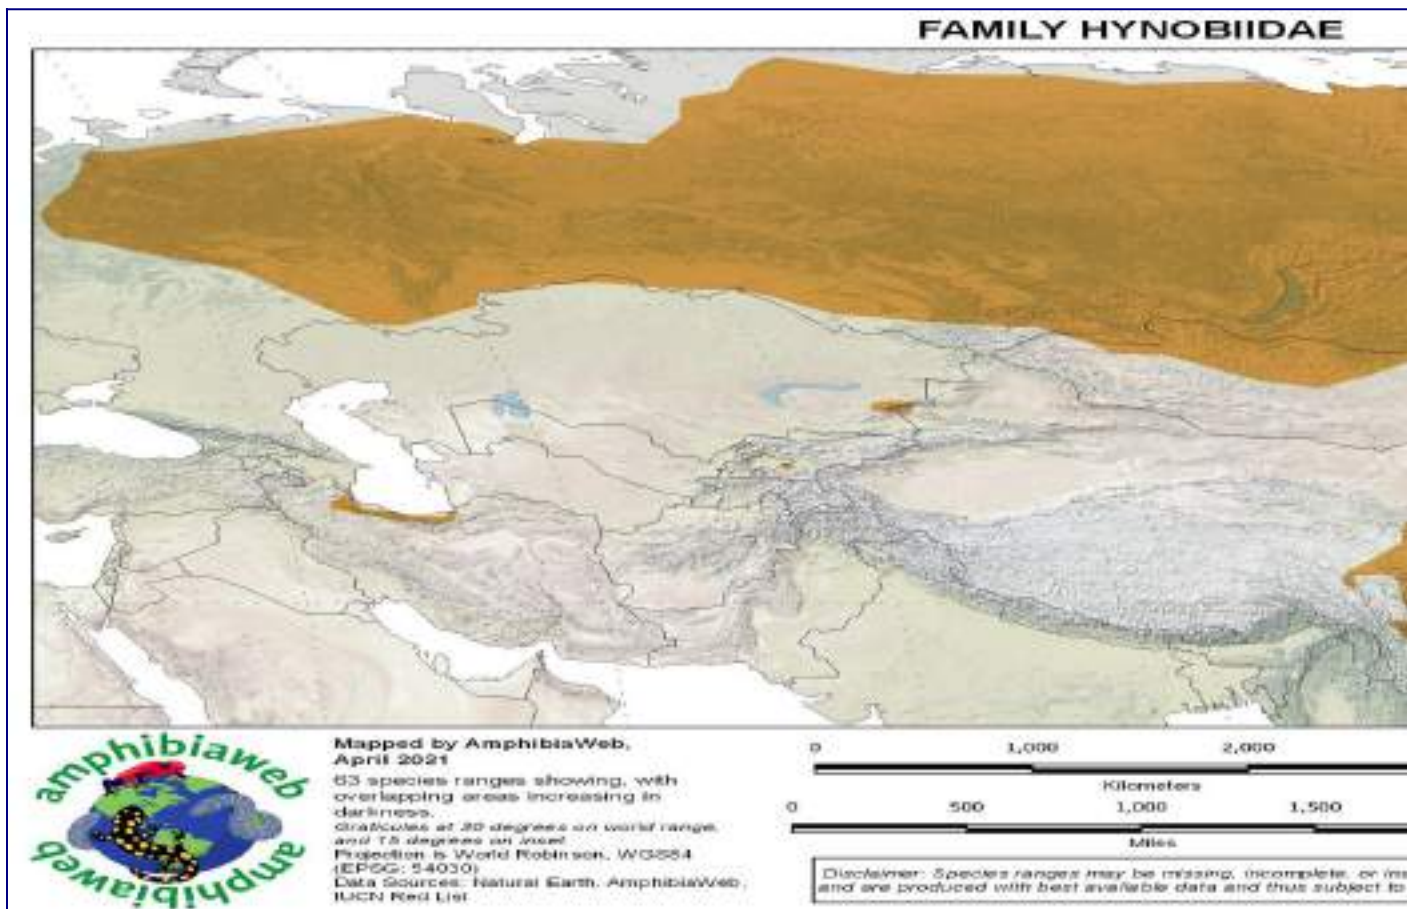

Members of this assemblage are divided into two subfamilies, the Onychodactyliini (*Onychodactylus*) and Hynobiini (*Hynobius*). Adults have eye lids and no gill slits. *Onychodactylus* (which also lacks lungs), *Liua shihi*, and a few *Batrachoseps* species grasp onto slippery rocks in their fast stream habitats. Externally, most species have a generalized tetrapod morphology with four legs and a long tail. Vomerine teeth (located on the roof of the mouth) are useful characters in distinguishing species. Some species, as other species, have displayed a cannibalistic larvae morphology in which they develop wider heads and more specialized morphological features (synapomorphies) for this group, but they do share some characters.

Written by AmphibiaWeb

## **Notable Family Characteristics**

- Both terrestrial and aquatic species
- Metamorphosis complete; adults lack gill slits
- Some morphological characters include: 1) septomaxillae present; 2) lacrimal present; 3) vomerine teeth present; 4) marginal teeth row; 5) ribs uncapitate; 6) eyelids present; 7) reduced or absent lungs (*Onychodactylus*); 8) external fertilization
- External fertilization, mating usually aquatic
- Distribution from eastern Europe through Asia, western Asia to Japan and Korea

## Plethodontidae

523 species in 28 genera

### Commonly Called Lungless Salamanders

The largest family of extant salamanders with over 500 species. All members of this family lack lungs, relying on skin and gill grooves, which aid in chemoreception. This group was once thought to have arisen out of the Appalachian Mountain region, a hotspot for this family. Members within this group have adapted to stream, arboreal, terrestrial, fossorial (underground), and aquatic environments.

the Hemidactylinae and Plethodontinae, of which the latter has species capable of ballistically projecting their tongues (tribe Bolitoglossini). Generalized in body form with four fingered toes (tribe Plethodontini), plethodontids cover the spectrum of salamander sizes. Most species are direct developers, with exceptions including *Gyrinophilus*, *Hemidactylium*, *Pseudotriton*, *Stereochilus*, and *Urspelerpes* genera.

With only a few of exceptions, this family is found in the New World and extends from southern Canada south to the Mediterranean in Europe (other members from Asia (*Karsenia*). It includes the only group of tropical salamanders which account for about 2/3 of the species.

### News Highlight:

December 5, 2022: Lungs have been independently lost in some members of all three major amphibian groups. Lungs have been lost in just one frog and one caecilian species. Lungs are absent in a larger number of salamanders. Lungs are absent in all hynobiids and all [species of the family Plethodontidae](#). [Lewis et al. \(2022\)](#) confirm that plethodontids are lungless but the process is reversed through programmed cell death (apoptosis) before they emerge from the egg. Genes involved in lung development in species that keep their lungs are also expressed in the vestigial lung development may be a necessary feature for the development of other organs, such as the heart. Because the common ancestor of the group between 66 million years ago (the timing of the first divergence even 66 million years ago (the timing of the split between Plethodontidae and its sister family, Amphiumidae), thus showing that lung development have been maintained for tens of millions of years despite the early loss of lungs in the

December 21, 2020: Salamanders differ from all other vertebrates in their range of genome size. At the lower end, they marginally overlap with frogs but the upper end is vastly greater and exceeds 100 pg. Because cell size is so enormous and this poses a problem for small species, which often show bizarre morphologies. This led to the idea of physical size. A study of tropical plethodontid salamanders ([Decena-Segarra et al 2020](#)), many of which are small, found that biological size (mean snout-vent/square root genome size) for 84 species, 60 newly studied. Many of the results would suggest. Biological size may be the most effective measurement for studying morphological constraints. (*Batrachoseps*. (DW)

June 22, 2020: Plethodontid salamanders use protrusible, ballistic tongues that display high performance in capturing prey. [Deban et al \(2020\)](#) show in a musculoskeletal and performance analysis that remarkable how the plethodontid salamanders has transformed a muscle-powered, musculoskeletal system capable of only moderate performance, an extreme-performance, spring-powered system that is thermally robust. Extreme examples exceed average. Intermediate forms are not found, suggesting that incipient elastic forms maybe short-lived. The result is consistent with remarkably specialized end points. [See a video of the cold-proof tongue in action](#) (DW)

February 25, 2019: Most salamanders must breathe in both water and air so they use gills, lungs, skin, and other respiratory organs during development. Plethodontid salamanders, also known as lungless salamanders, do not even have lungs and instead breathe near the back of their mouth. Until recently, the molecular changes that allow lungless salamanders to breathe were completely unknown. [Lewis et al. \(2018\)](#) show that lungless salamanders express a novel paralogue of the SFTPC gene in areas (such as the skin) that lungless salamanders use to breathe. In other vertebrates, SFTPC is critical for lung development. This new paralogous gene appears to be found only in salamanders, but, similar to SFTPC, in lungless salamanders. [al. \(2018\)](#) propose that this new gene paralogue may be one reason lungless salamanders have thrived in aquatic environments. (M Womack)

July 23, 2018: How will salamanders deal with climate change? A new experimental study ([Riddell et al. 2018](#)) shows remarkably plastic responses to ecological conditions, which bode well for anticipated increases in climate change. The study integrated physiology and behavior into a mechanistic species distribution model and predicted extinction risk based on

energy balance both with and without plasticity. The important conclusion is that incorporating plasticity reduces the risk of extinction. These findings help understand how salamanders in the southern Appalachian biodiversity hotspots have survived recent climate change events. They likely "sheltered in place", as suggested by the many phylogeographic studies showing substantial genetic structure. [the press release](#). (DW)

March 14, 2016: Plethodontid salamanders are more agile than other salamanders and they are known to be good jumpers. A new study has studied jumping in six species (three genera). All were capable of jumping by lateral body bending followed by a powerful push off the ground into the air. Most likely force to propel the animal is applied through one or both hind limbs. Salamander jump height is scaled with body size and forelimb length. Species did not differ in any other aspects of performance. Larger salamanders are slower. No correlation was found between tail length, or even presence of a tail, and jumping performance. This helps us understand how salamanders maintain jumping performance no matter the size. (DW)

November 28, 2016: Minute salamanders of the genus *Thorius* were once very common in montane habitats of the Mexican Plateau, where they have experienced an adaptive radiation in miniature. Molecular data have revealed that these species, which are then discerned to differ in morphology, ecology, elevational distribution, etc. Species detection is difficult due to the rarity of these tiny animals. [Parra-Olea et al. \(2016\)](#) revises the taxonomy of the southern and easternmost species, recognizing two species while describing and naming three others. The new species all are considered to be critically endangered, on the brink of extinction from as yet undetermined causes. (DW)

Written by AmphibiaWeb

## Notable Family Characteristics

- All species are lungless
- Species have diversified into a wide variety of habitats, such as stream, arboreal, terrestrial, fossorial (burrowing), and aquatic habitats
- Morphological characters include: 1) pterygoid absent; 2) naso-labial groove present; 3) lacrimals absent; 4) preopercle and opercle elements fused; 5) elongate, up to 60 vertebrae; 6) teeth have a distinct crown and pedicel; 7) males possess a large, complex, and often colorful nuptial pad
- Fertilization internal
- Direct development in most species
- Distribution predominantly North America through South America to Bolivia and Brasil, with exceptions in Japan (*Karsenia*) and some species of *Hydromantes* in Europe

# Proteidae

8 species in 2 genera

## ***Commonly Called* Mudpuppies, Waterdogs, Olms**

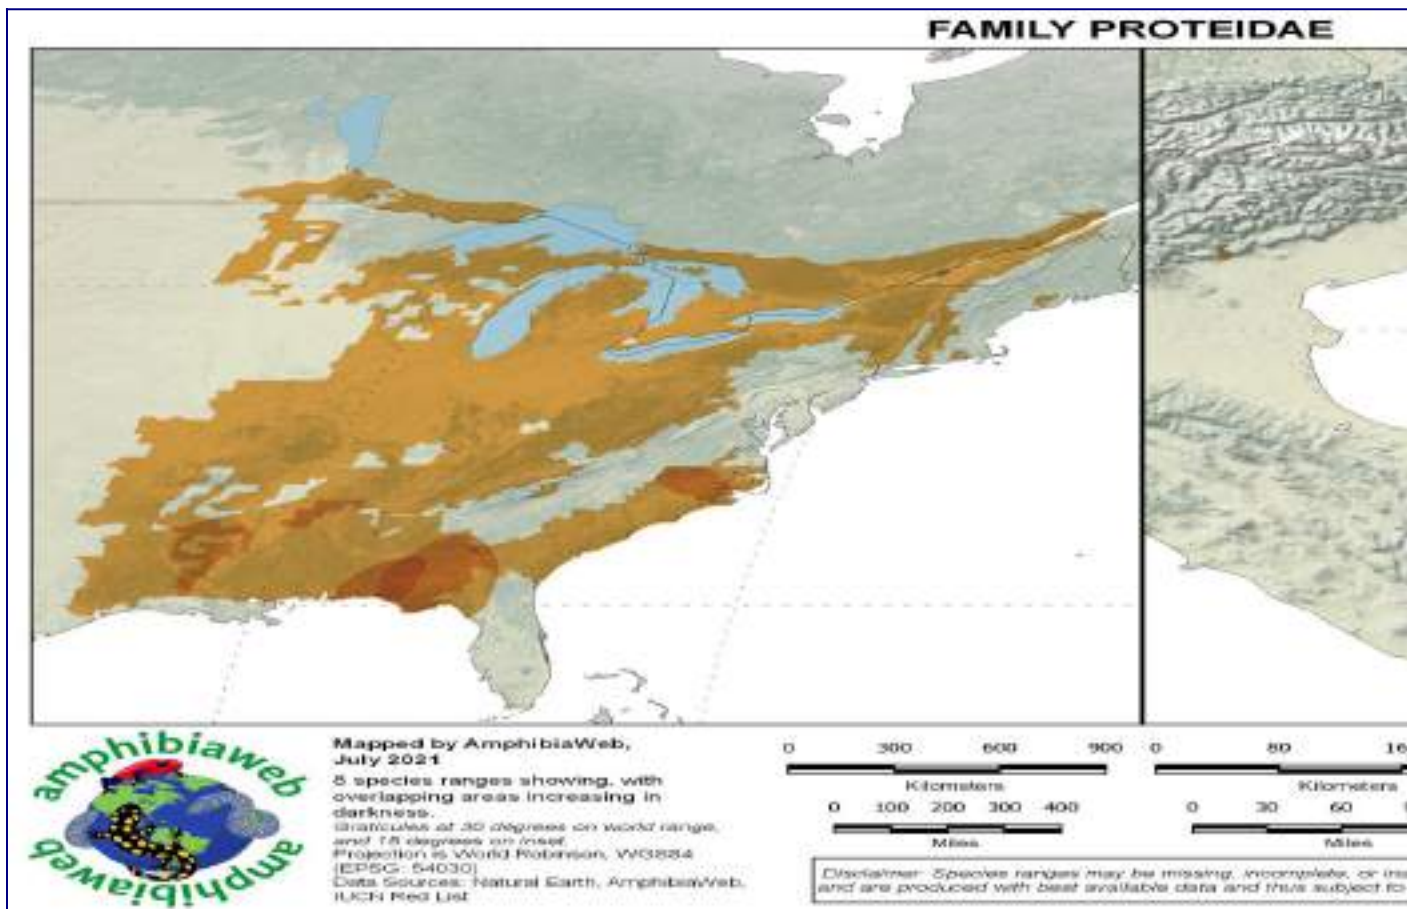

This family is exclusively aquatic, paedomorphic salamanders with large, red, filamentous, external gills and (Proteus, up to 200 mm) and North America (Necturus, up to 400 mm). One species of *Proteus* and five species of *Necturus* are found in Europe. The blind cave salamander, *Proteus anguinus*, is perhaps the rarest and strangest of all extant salamanders in museum collections. It lives in caves. Little information is available on the reproductive biology of these salamanders, although *P. anguinus* has been observed at the birth of advanced young.

Written by AmphibiaWeb

## **Notable Family Characteristics**

- Aquatic
- External gills, elongate form with laterally compressed tails
- Habitat includes lakes, rivers and streams or caves and underground water sources as in *Proteus*
- Nocturnal
- Internal fertilization
- Some morphological characters include: 1) maxillae, prefrontals, septomaxillae, ypsiloid cartilage, and on splenial and pterygoid; 3) two pairs of larval gill slits; 4) external gills present; 5) reduction in number of chromosomes.
- Disjunct distribution between eastern North America and Europe

## Rhyacotritonidae

4 species in 1 genus

**Commonly Called Torrent Salamanders, Seep Salamanders**

*Rhyacotriton olympicus*  
Photo by John P. Clare  
([Click for family gallery](#))

This monotypic family are species of small (ca. <80 mm snout-vent length) semi-aquatic salamanders with aquatic larvae. They may represent remnants of an early radiation of salamanders and are found exclusively in old-growth humid forests of conifers. Members are small and stocky bodied, with large eyes and a semi-aquatic lifestyle and vestigial lungs. Fertilization is internal, and large, unpigmented eggs are laid beneath rocks or in crevices of cold, clear water.

They occur exclusively in the coastal coniferous forests of the Pacific Northwest in North America. These species are genetically distinct from one another and generally do not occur sympatrically.

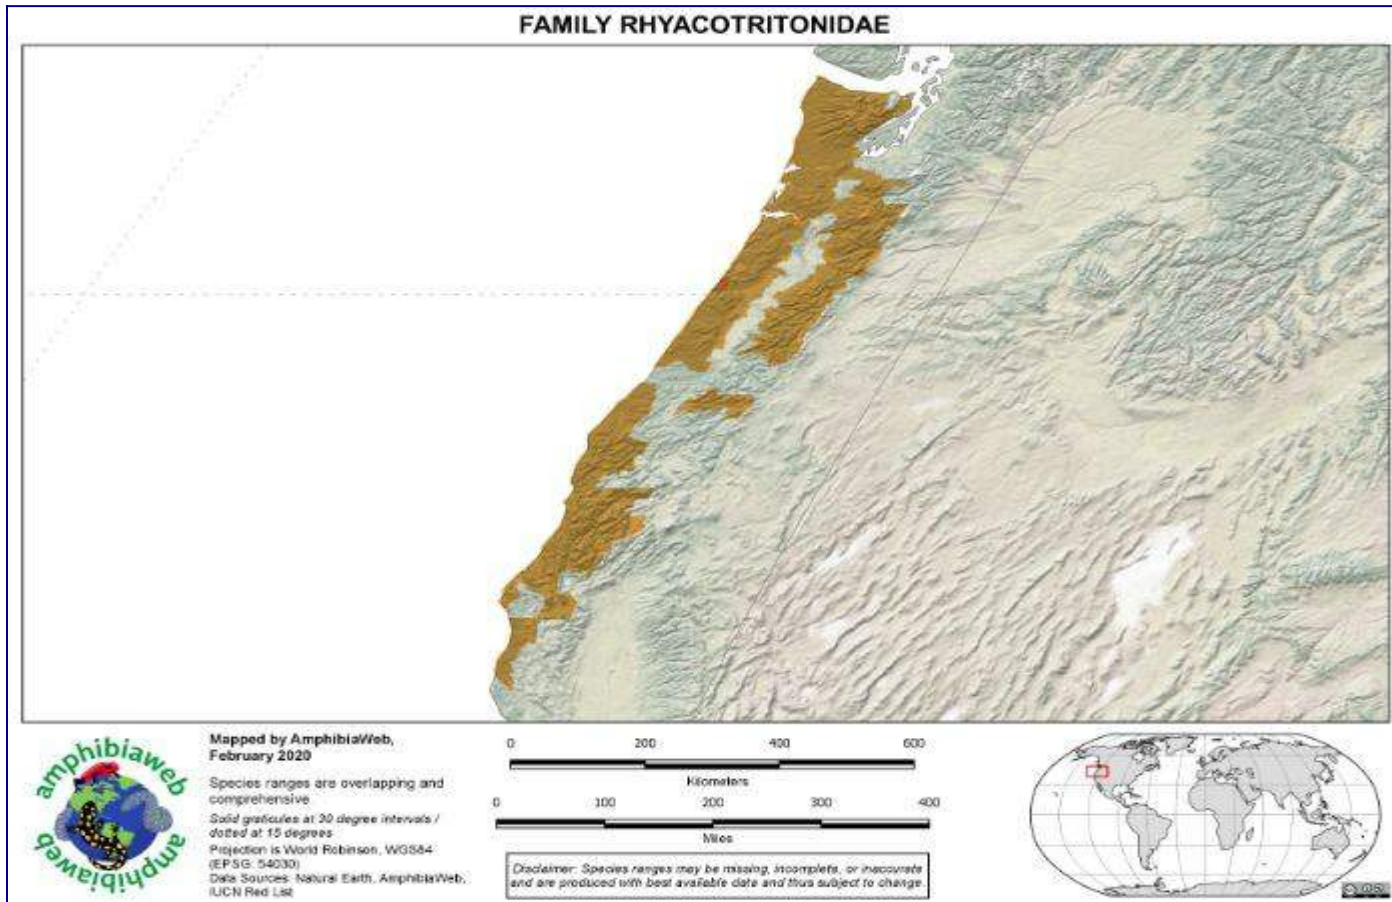

Written by AmphibiaWeb

### Notable Family Characteristics

- Found in cold, shaded streams or nearby leaf litter in temperate wet forests of typically old-growth conifers
- Larvae fully aquatic and may take 3-5 years to metamorphosis
- Internal fertilization
- Morphological characters are: 1) squared glands posterior to vent in males; 2) absence of operculum and associated opercular muscle (only seen in some hynobiids); 3) reduced

lungs (as seen in plethodontids and hynobiids)

- Coloration is typically dark dorsum, some species may be flecked, and bright yellow / orange or yellow-green venter
- Distribution limited to western North America, in coastal Pacific Northwest

# Salamandridae

150 species in 22 genera

## ***Commonly Called True Salamanders, Newts, European Salamanders***

Salamandrids are small to medium sized (*Salamandra* and *Pleurodeles* reach more than 200 mm) terrestrial or aquatic. They are found in Europe, North America, and Asia, although the distribution of *Salamandra* and *Pleurodeles* reaches North Africa, and the genera *Notophthalmus* and *Ambystoma* have toxic skin secretions. Many Salamandrids develop dorsal body and tail fins when they return to an aquatic life as adult newts. Lungs are present in juveniles and adults. Salamandrids achieve internal fertilization through the amplexus. Mating is often accompanied by a courtship dance.

The family is organized into three subfamilies: Salamandrininae, Salamandrinae, and Pleurodelinae. Salamandrininae has only one genus, *Salamandrina*, known from the mountains of Italy. Salamandrinae species are generally found in western Asia and northern Africa. Pleurodelinae species are generally known as Newts, with a distinct terrestrial phase when adults return to water for breeding.

### **News Highlight:**

June 5, 2017: North American newts, *Notophthalmus*, form a relatively young clade that appears to be evolving rapidly (Yuan et al. 2017). Derived taxa are becoming more aquatic. Males are diverging from females as a result of disruptive selection. Sexual dimorphism is manifest in feeding-related head morphology. The authors suggest that sexual dimorphism is a result of adaptation, environmental change and adaptive radiation, in contrast to some theoretical work suggesting a developmental constraint.

February 6, 2023: Evolutionary history and biogeographic patterns give us insight into how species respond to environmental changes in a shared landscape, and these in turn can provide a guide for conservation management. In southern China, the landscape has changed in elevation ranging from an average of 4000 m a.s.l to sea level. Yuan et al. (2022) used multi-locus data to investigate phylogeographic patterns in the southern Chinese newt genera of *Cynops*, *Paramesotriton*, and *Amphispelta*. Major geological events, such as the uplift of the Qinghai-Xizang (Tibet) Plateau. Furthermore, variations in montane/submontane forest with lowland areas resulted in barriers that act as both ‘museums’ or refugia.

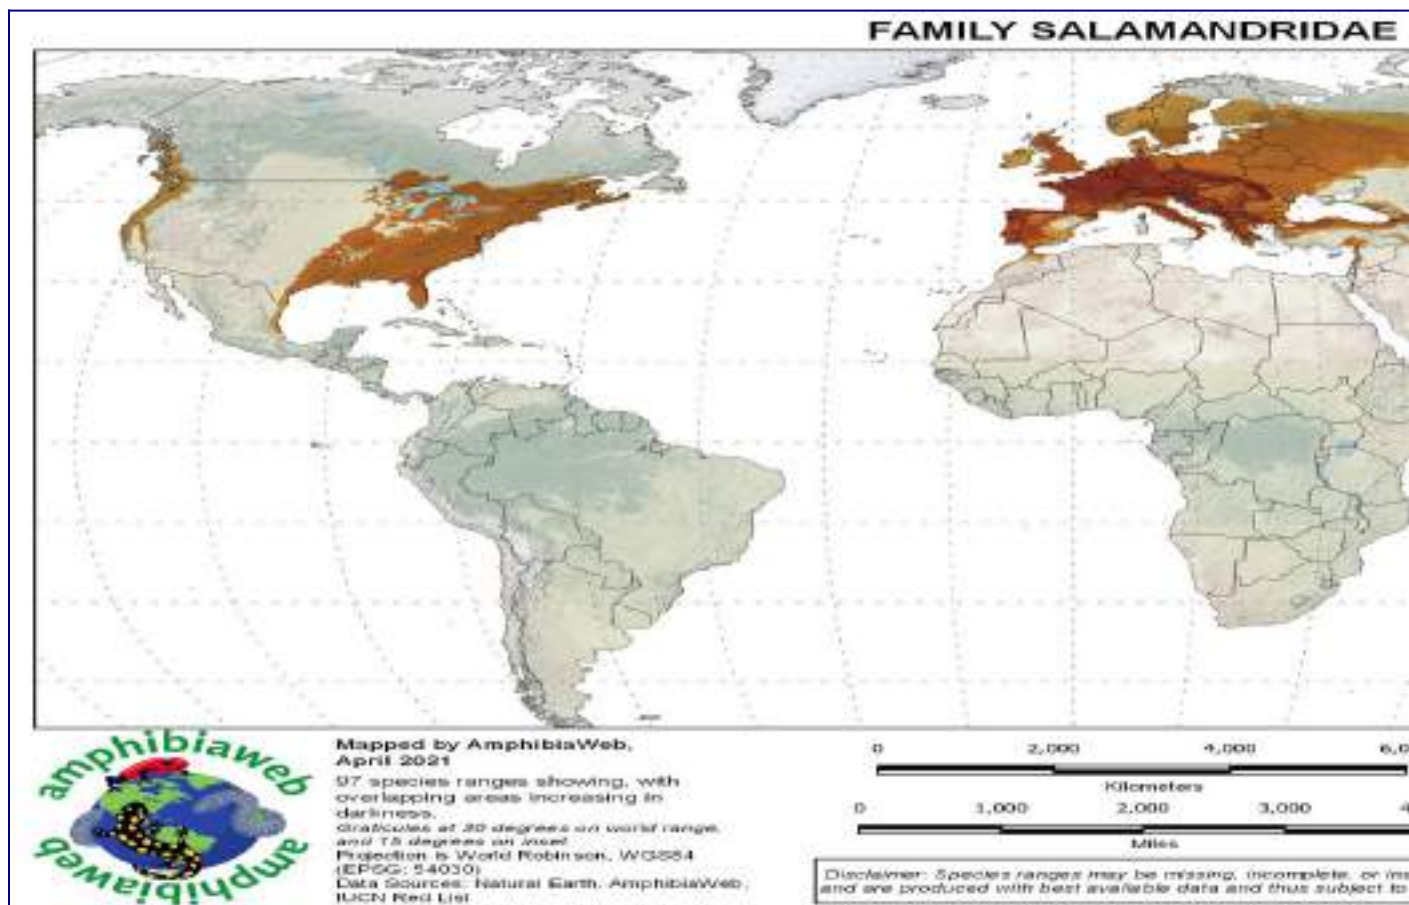

diversification. These findings can provide a backbone for genetically informed management plans, but habitat disturbance and over-harvesting of vulnerable species. (Written by Ann Chang)

Written by AmphibiaWeb

## Notable Family Characteristics

- Aquatic and terrestrial species
- Biphasic or triphasic life cycles, where larvae are fully aquatic, and may metamorphose into terrestrial and return to aquatic form as adults, either seasonally for breeding or permanently
- Males court females for breeding
- Many possess highly toxic secretions from poison glands in their skin
- Fertilization is internal through a spermatophore
- Some morphological characters for the group are: 1) vomerine teeth extending posteriorly on lateral edge of maxilla; 2) arch present; 3) vertebrae opisthocoelous; 4) costal grooves above the ribs are absent; 5) functional lungs are present.
- Global distribution in Europe, western Asia, Asia, northern Africa and North America

## Sirenidae

7 species in 2 genera

### Commonly Called Sirens

*Pseudobranchius axanthus*

Photo by Todd Pierson

(Click for family gallery)

These are elongate, eel-like, small to large (750 mm snout-vent length) aquatic salamanders with external gills. The pelvic girdle and hind limbs are absent in all species but small forelimbs are present. Members of this family

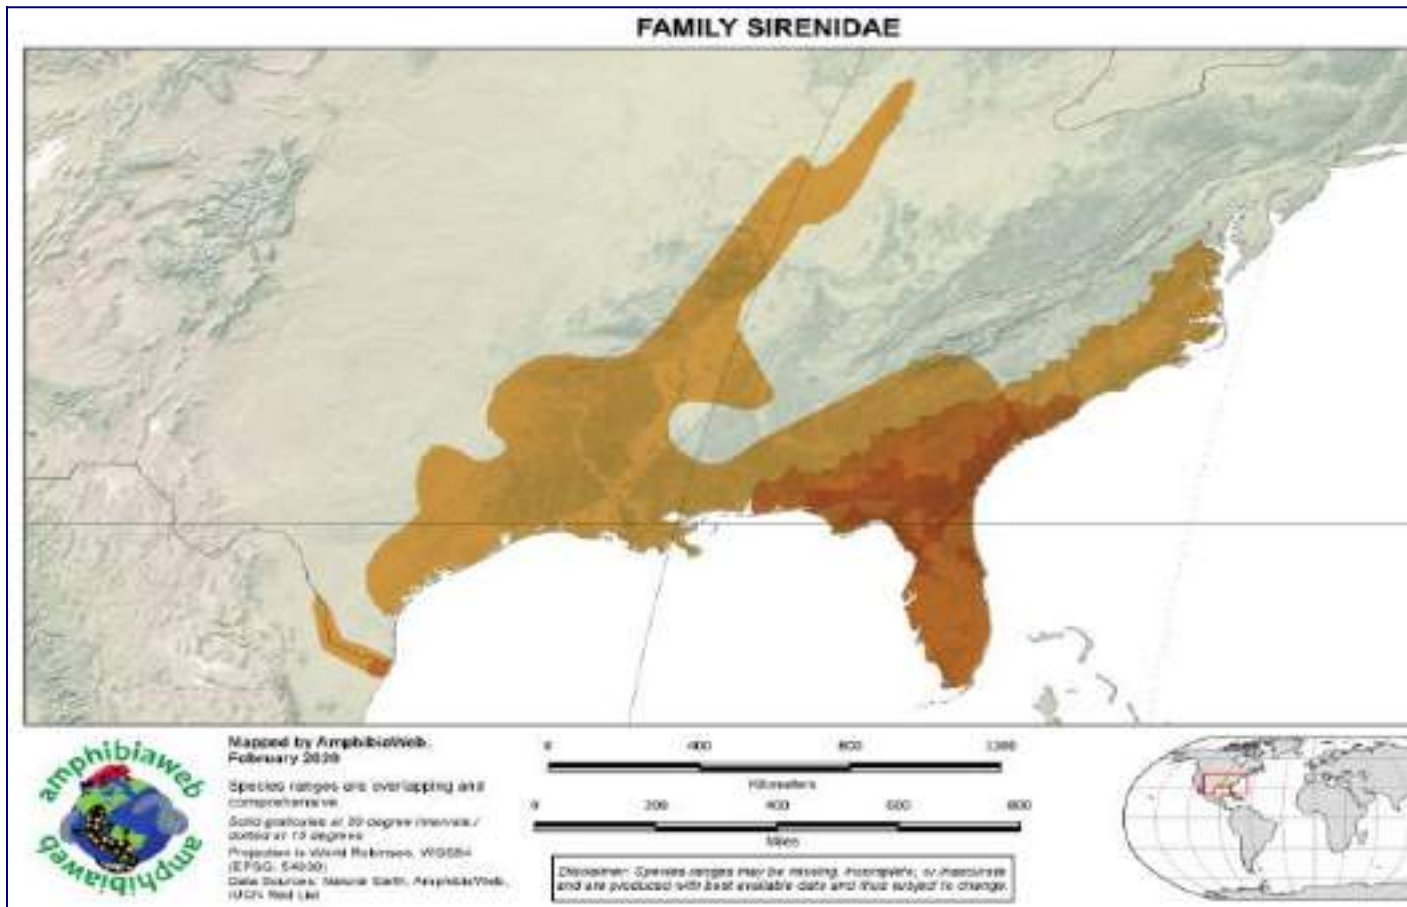

paedomorphic, with adults retaining larval features such as gills, a lateral line system, and suction feeding (although they also possess moving jaws).

They are distributed in the southeastern United States and northern Mexico and usually are considered to be the closest group to all other living salamanders. Two genera belong to this family, *Siren*, and *Pseudobranchius*.

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Aquatic
- Inhabits both permanent and semi-permanent water bodies such as marshes, wetlands, ponds, canals, and lakes, preferring heavy vegetation
- Paedomorphic adults
- Generally nocturnal
- Lays eggs
- Some morphological characters for this group include: 1) non-pedicellate teeth; 2) maxillae reduced to tiny-free elements; 3) no premaxillary or maxillary teeth; 4) no pelvic girdle; 5) no hindlimbs, but small forelimbs.
- Paedomorphic characteristics include: external gills, a lateral line system, and suction feeding
- Distribution limited to southeastern USA and extreme northeastern Mexico in North America

Caecilians

## Caeciliidae

54 species in 2 genera

### *Commonly Called Common Caecilians*

*Caecilia thomsoni*  
Photo by Esteban  
([Click for family](#))

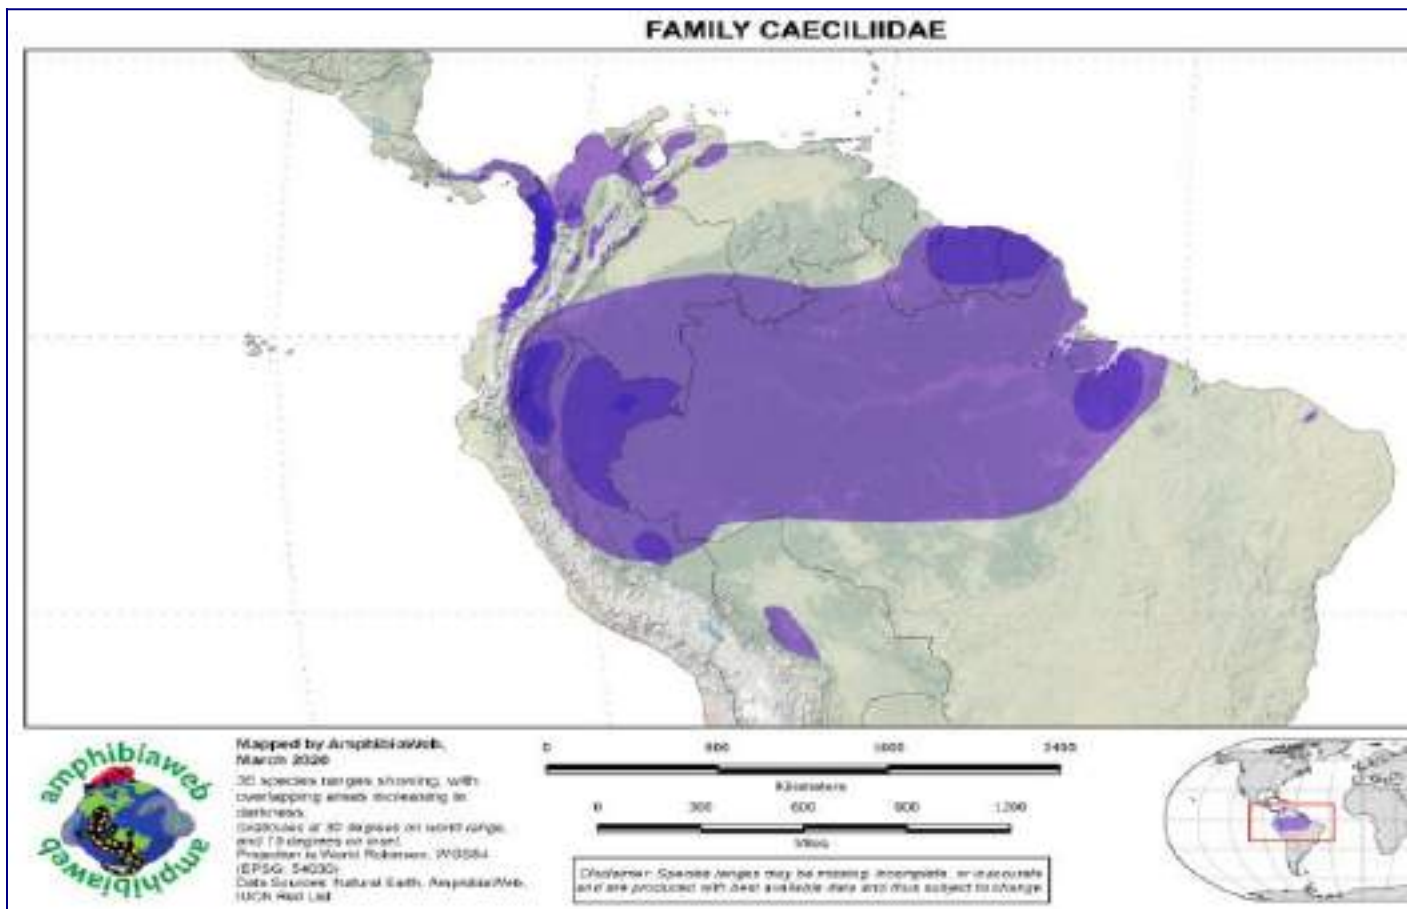

The family Caeciliidae underwent substantial taxonomic revision in Wilkinson et al. (2011). These species are slender, some quite large (up to 1.5 m in *Caecilia thomsoni*) and vary from dark bluish slate to light gray in color with visible annuli.

Much of the natural history and biology of this fossorial family is unknown.

Written by AmphibiaWeb.

### Notable Family Characteristics

- Morphological distinguished by the following combination: imperforate stapes, inner mandibular teeth, eyes surrounded or covered by the maxillopalatine, and monocusped teeth
- Generally known from tropical forests, both primary and secondary
- Oviparity known in at least *C. orientalis*
- Fossorial
- Distribution in Central and South America

## Chikilidae

**4 species in 1 genus**

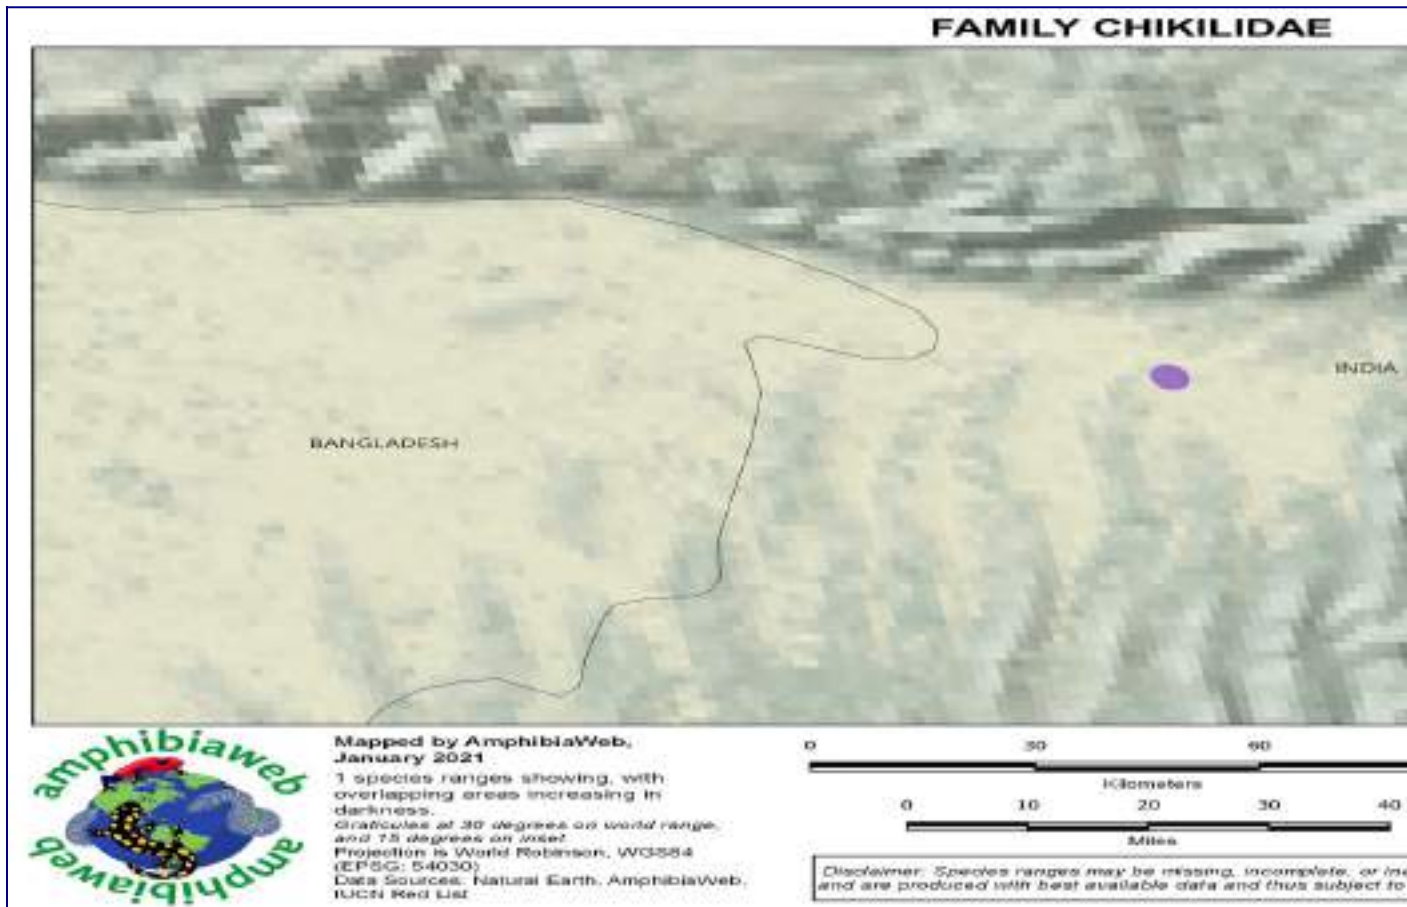

### ***Commonly Called Northeast Indian Caecilians***

This family was recently described in 2012 (Kamei et al) after extensive survey efforts in the Northeast India. the caecilian *Chikila fulleri*, the first described species in the new family Chikilidae. From molecular phylogenetic and comparative cranial anatomy, they determined chikilids were more closely related to the African family Herpessidae. Further, they propose this family represents an ancient radiation in wet tropical forests and thus evidence for the presence of a new family in the Indian region.

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Family named for Chikila, a northeastern (Meghalaya state) Indian tribal name for the included caecilians
- Oviparous
- Direct development
- Lacks prefrontals with two rows of teeth in the lower jaw
- Stapes perforate, separate premaxillae and nasals
- Lacks the multiple antotic foramina seen in Herpessids
- Distribution known only to Northeastern India (Arunachal Pradesh, Meghalaya, Nagaland and Tripura) and Bangladesh

# Dermophiidae

15 species in 4 genera

## ***Commonly Called* Neotropical and Tropical African Caecilians**

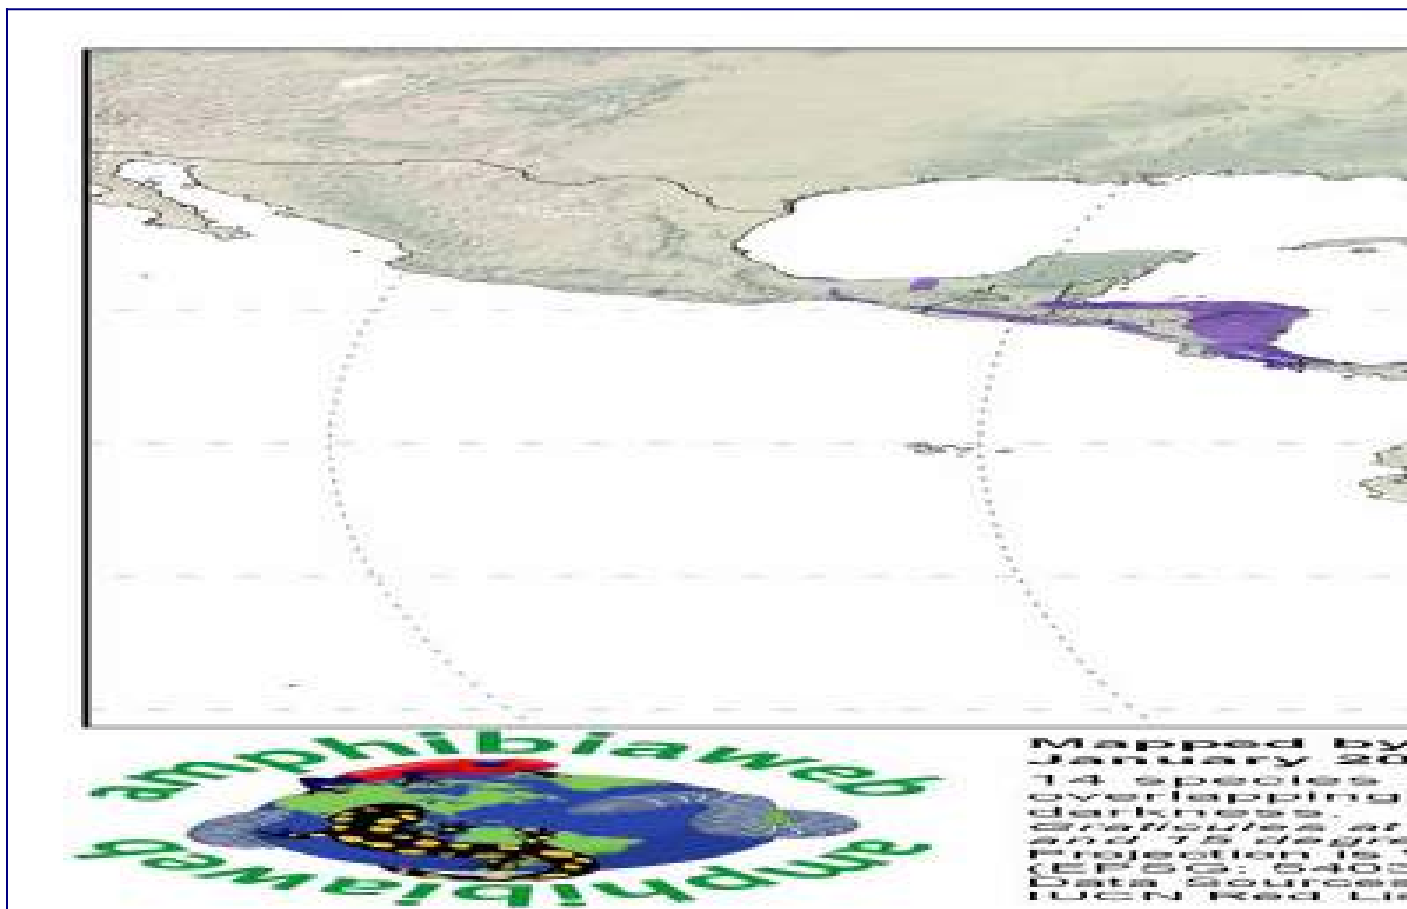

These are generally robust, terrestrial caecilians, and like the others of their order, are legless, tailless with vis

They are sister to Siphonopidae.

Written by AmphibiaWeb.

### **Notable Family Characteristics**

- Secondary annuli and annular scales
- Viviparous
- Fossorial
- Generally confined to the wet tropics
- Distribution in Africa, Central America, and South America

## Grandisoniidae

25 species in 6 genera

### *Commonly Called Indo-African Caecilians*

These are small, slender caecilians with patchy distribution in India, Africa, and the Seychelles islands (Wilkinson, 2010).

This family is distinguished by the following combination of characters: imperfect stapes, presence of inner nuchal fold, and presence of a large, circular, and highly reflective, tympanic membrane.

Formerly known as Indotyphlidae, Dubois et al. (2021) determined the appropriate name to be Grandisoniidae.

#### **News Highlight**

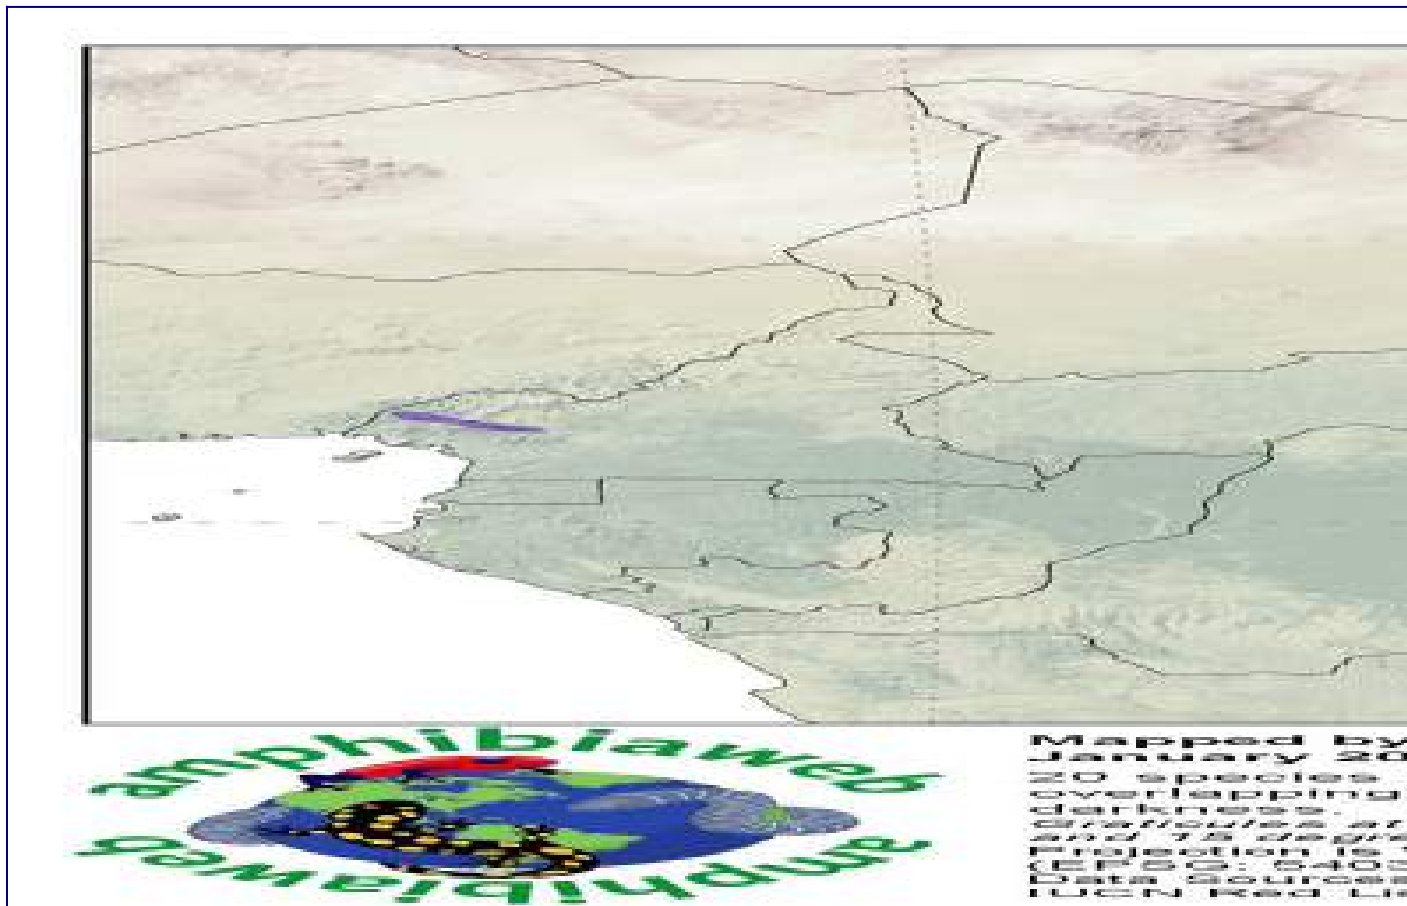

July 11, 2016: Indian biodiversity is concentrated in three major, disjointed, wet-zones: North-East India, Western Ghats, and the Western Ghats. A team of researchers from the Indian Institute of Technology (IIT) Bombay and the University of Cambridge, UK, have built a molecular clock. Although the mechanism is still unclear, they found that the only known Eastern Hemisphere caecilian, *Grandisonia*, is a member of the family Grandisoniidae.

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Inhabits moist tropical rainforests
- Fossorial
- Viviparity and oviparity
- Many species known to show egg-guarding or other parental care

- Distribution is patchy with members in southern and northeastern India, Seychelles Islands, and Africa

## Herpelidae

11 species in 2 genera

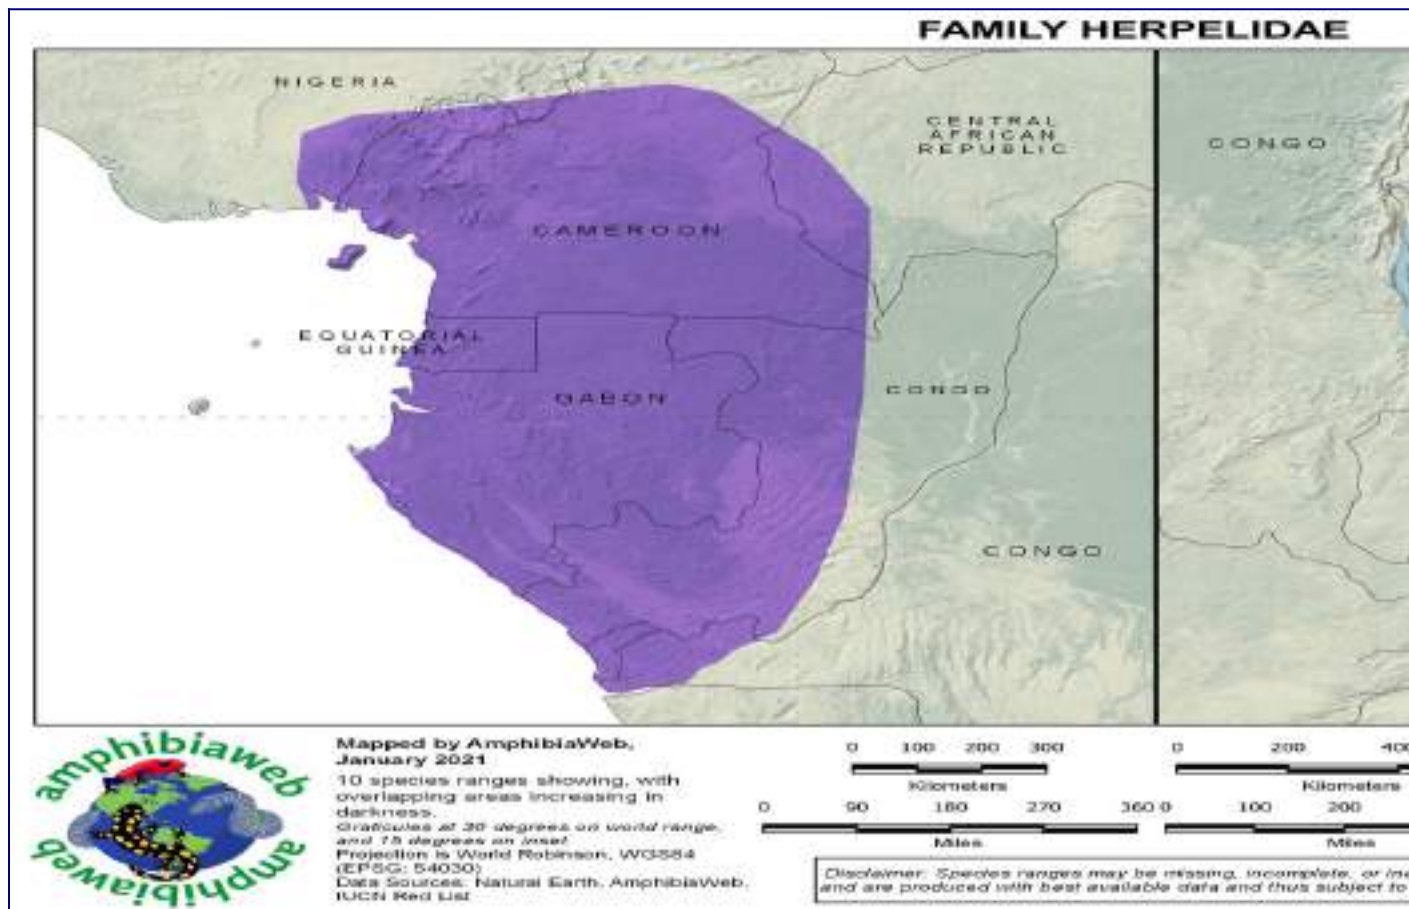

## ***Commonly Called African Caecilians***

These slender African caecilians (35 cm or less) are poorly known; much of their natural history is surmised from *Boulengerula taitana*, which exhibits both egg guarding in an underground nest as well as parental care afterward when the female grows a new skin. They have been found in mountainous as well as agricultural areas of East Africa.

The two genera are disjunctly distributed in Africa, with *Herpele* from West Africa and *Boulengerula* in East Africa. Written by AmphibiaWeb

### **Notable Family Characteristics**

- Fossorial
- Egg guarding in an underground nest by the female (known in *Boulengerula taitana*)
- Female feeds young with a lipid-rich skin secretions (known in *Boulengerula taitana*)
- Distinguishable by the following combination of characters: 1) perforate stapes, 2) multiple, small antorbital foramina, 3) septomaxillae or separate prefrontals. Eyes concealed under bone
- Distribution in Africa; *Herpele* known only from West Africa and *Boulengerula* in East Africa

## Ichthyophiidae

59 species in 2 genera

### ***Commonly Called* Asian Caecilians, Fish Caecilians, Asian Tailed Caecilians**

Ichthyophiids can be diagnosed by the combination of partial external division of the atrium and a long anterior opening lies between the nostrils and the eye or closer to the eye, or anterior on the snout below the nostril (as

Much is still unknown about the natural history of these species.

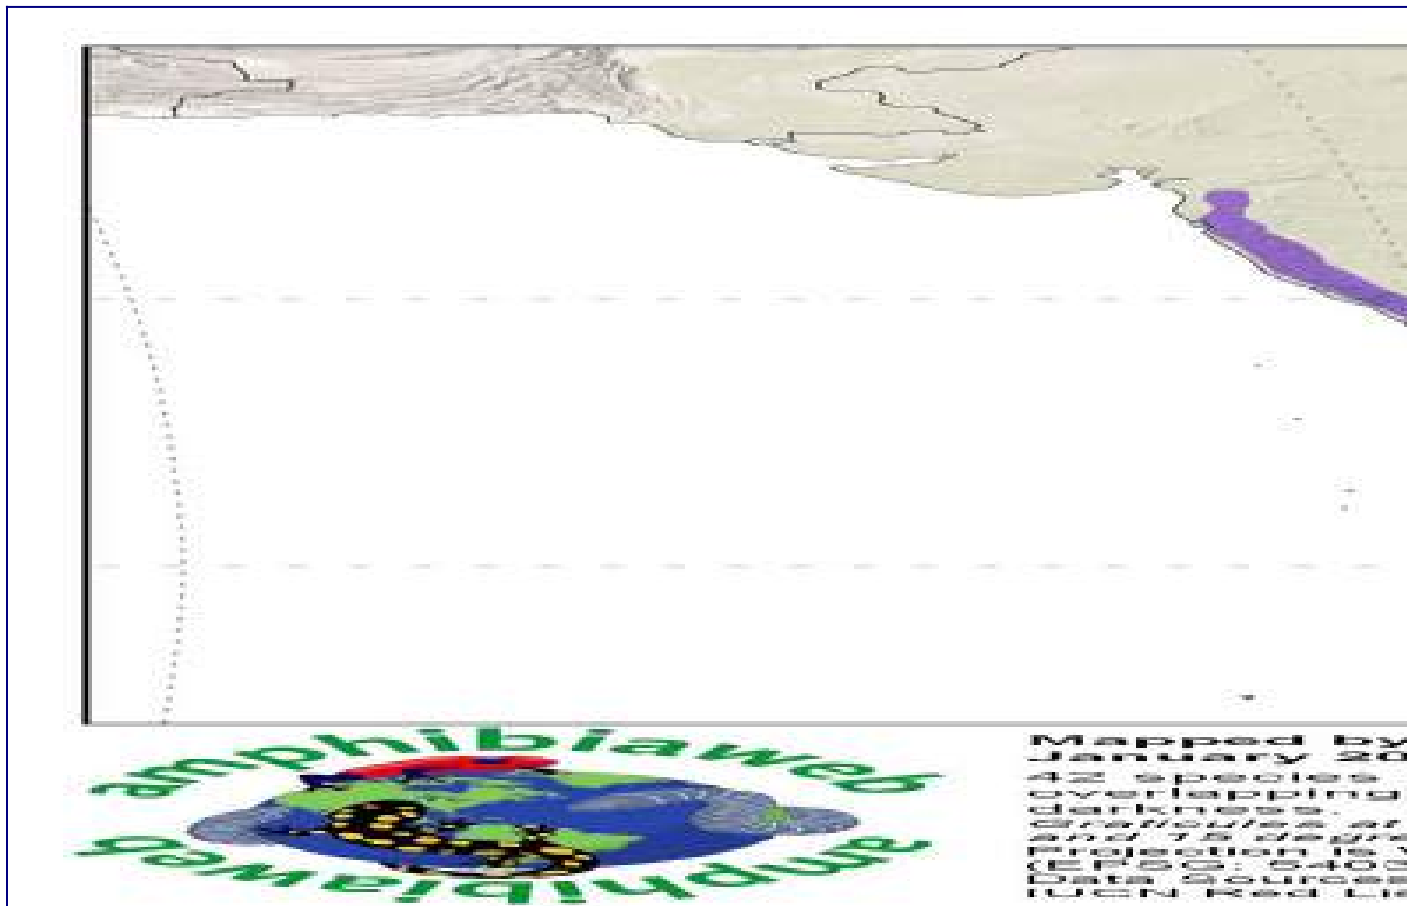

Ichthyophiids are found in South and Southeast Asia. The family Ichthyophiidae has undergone some taxonomic

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Fossorial, Terrestrial
- Occurs in a variety of habitat, primary and secondary forests, agricultural fields or plantings (e.g., tea plantations)
- Adults have a true tail although short with caudal vertebrae
- Eggs are laid in moist soil or underground chambers near water where the female cares for the eggs until they hatch
- Morphological features include: 1) distinct primary annuli, divided by secondary grooves; 2) generally

- Distribution limited to South and Southeast Asia

## Rhinatreumatidae

15 species in 3 genera

***Commonly Called* Tailed Caecilians, American Tailed Caecilians**

*Epicrionops* sp.

Photo by Moraes et al 2011

[\(Click for family gallery\)](#)

The family Rhinatrematidae is comprised of genera of medium-sized caecilians (ranging from 161-328 mm) with short tails (post-cloacal vertebrae present) as with Ichthyophiidae. Members of this family have primary annuli subdivided by secondary and tertiary annuli. Dermal scales occur in all annuli. The mouth is terminal (not covered in more derived caecilians) and the tentacular opening is adjacent to the eye (considered to be the ancestral condition relative to its more anterior position in other caecilians). Rhinatrematids have partially open temporal regions (zygokrotaphy) on the skull. Zygokrotaphy along with a terminal mouth may suggest they are not highly specialized for burrowing. All caecilians have a dual jaw adducting mechanism, which is unique in vertebrates. In rhinatrematids, the

muscle is made up of one bundle (all other caecilian clades have two bundles). Rhinatrematids have a ground gray or grayish to purplish; some exhibit a yellow lateral stripe.

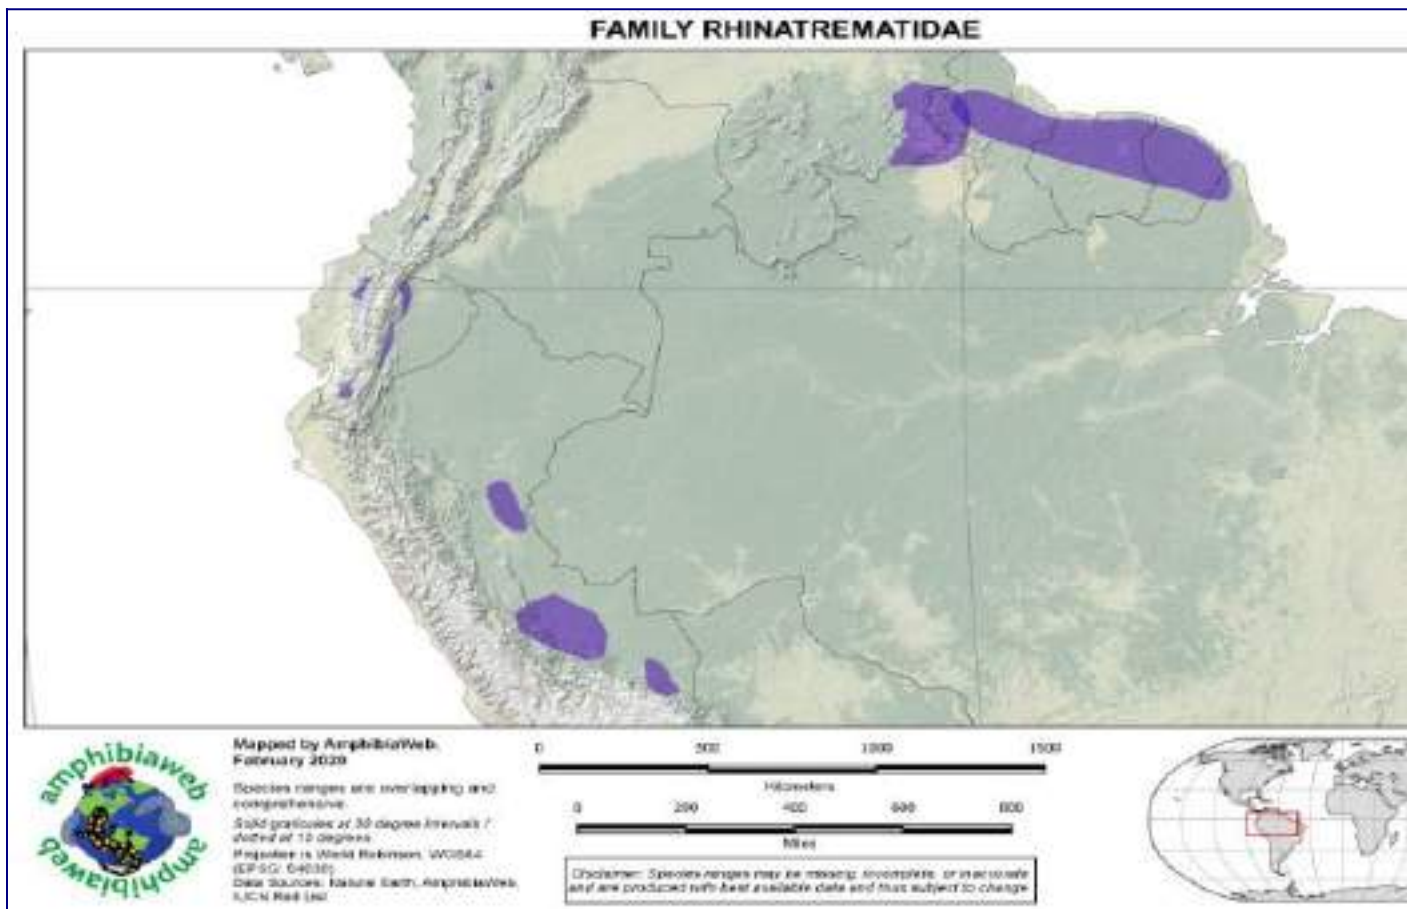

Little is known of their natural history.

Their distribution ranges from northern South America through Brazil, Colombia, Ecuador, Peru, Surinam, Gu French Guiana, and Venezuela. Like most caecilians, these are found in tropical forests with dense forest litter vegetation. The presence of larvae indicates that they are egg layers.

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Fossorial, may be Terrestrial
- Found in the leaf litter and vegetation of tropical forests
- Egg layers with free-living larvae
- Morphological features include: 1) primary annuli present subdivided by secondary and tertiary annuli, with dermal scales in all annuli; 2) mouth is terminal (not countersunk as in more derived caecilians); 3) tentacular opening adjacent to the eye; 4) skull has open temporal regions (zygokrotaphy); 5) dual jaw adducting muscle is made up of a single bundle; 6) caudal vertebrae and tail with downward projecting arches (haemal arches)
- Distribution limited to South America

## Scolecophoridae

6 species in 2 genera

**Commonly Called Buried-eyed Caecilians, Tropical Caecilians**

*Scolecophorus vittatus*  
Photo by John Measey  
([Click for family gallery](#))

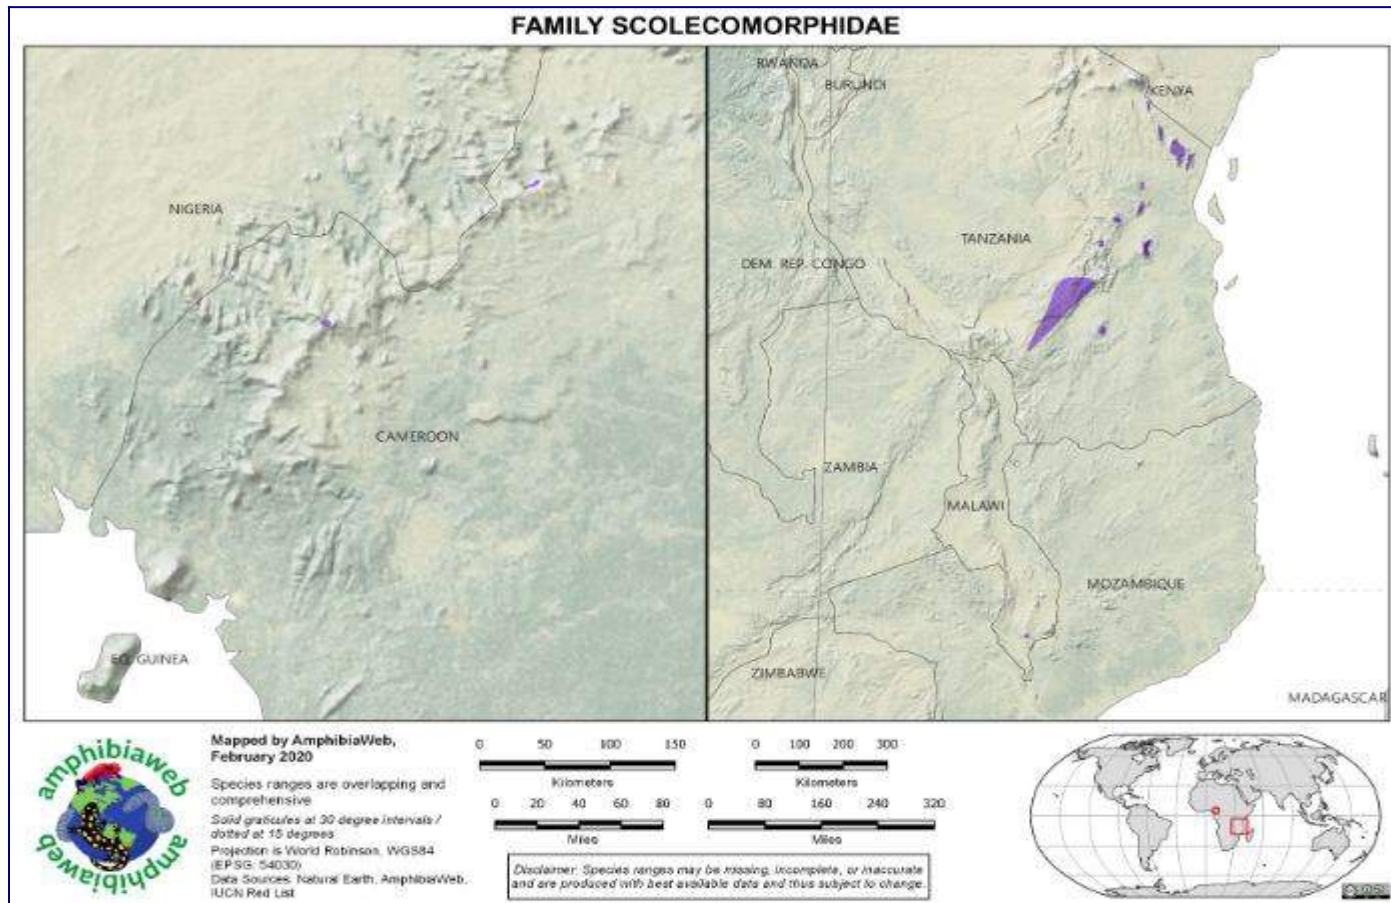

The family Scolecophoridae consists of small to medium-sized caecilians (ranging from 270-448 mm), with counter-sunk lower jaws and tentacle-like openings placed very far forward on the snout. Orbits are absent; eyes are connected basally to the tentacle and are protruded along with the tentacle. They lack a stapes as well as secondary and tertiary annuli. Annular grooves lack dermal scales. Females tend to have more vertebrae than males, and as a result are longer and larger. Of the two genera in this family, *Scolecophorus* is viviparous. Much is unknown of their natural history and biology.

Their distribution is restricted to western and eastern equatorial Africa.

Written by AmphibiaWeb

## Notable Family Characteristics

- Fossorial
- Viviparity in *Scolecophorus*, but oviparity may exist in *Crotaphatrema*
- Some evidence for maternal dermatophagy, but more information is needed
- Morphological characters include: 1) counter-sunk lower jaws; 2) absent orbits and eyes beneath bone; 3) eyes are connected basally to the tentacle and protrude along with it; 3) tentacle placed far forward; 5) only primary annuli present; 6) absent or vestigial dermal scales only; 7) stapes in middle ear absent; 8) no true tail
- Distribution limited to equatorial Africa

## Siphonopidae

28 species in 5 genera

### ***Commonly Called South American Caecilians***

Siphonopids, small to medium sized (112 mm to 120 mm total length) caecilians, burrow in moist humid trop following combination of characters: oviparity, imperforate stapes and lack of inner mandibular teeth. Species unknown. Many species exhibit maternal dermatophagy, a reproductive behavior in which the young feed on using a unique set of "fetal" multicuspid teeth (e.g., *Microcaecilia dermatophaga*, *Siphonops annulatus*).

Siphonopids were previously placed in Caecilidae until Wilkinson et al (2011); subsequent studies placed Sip

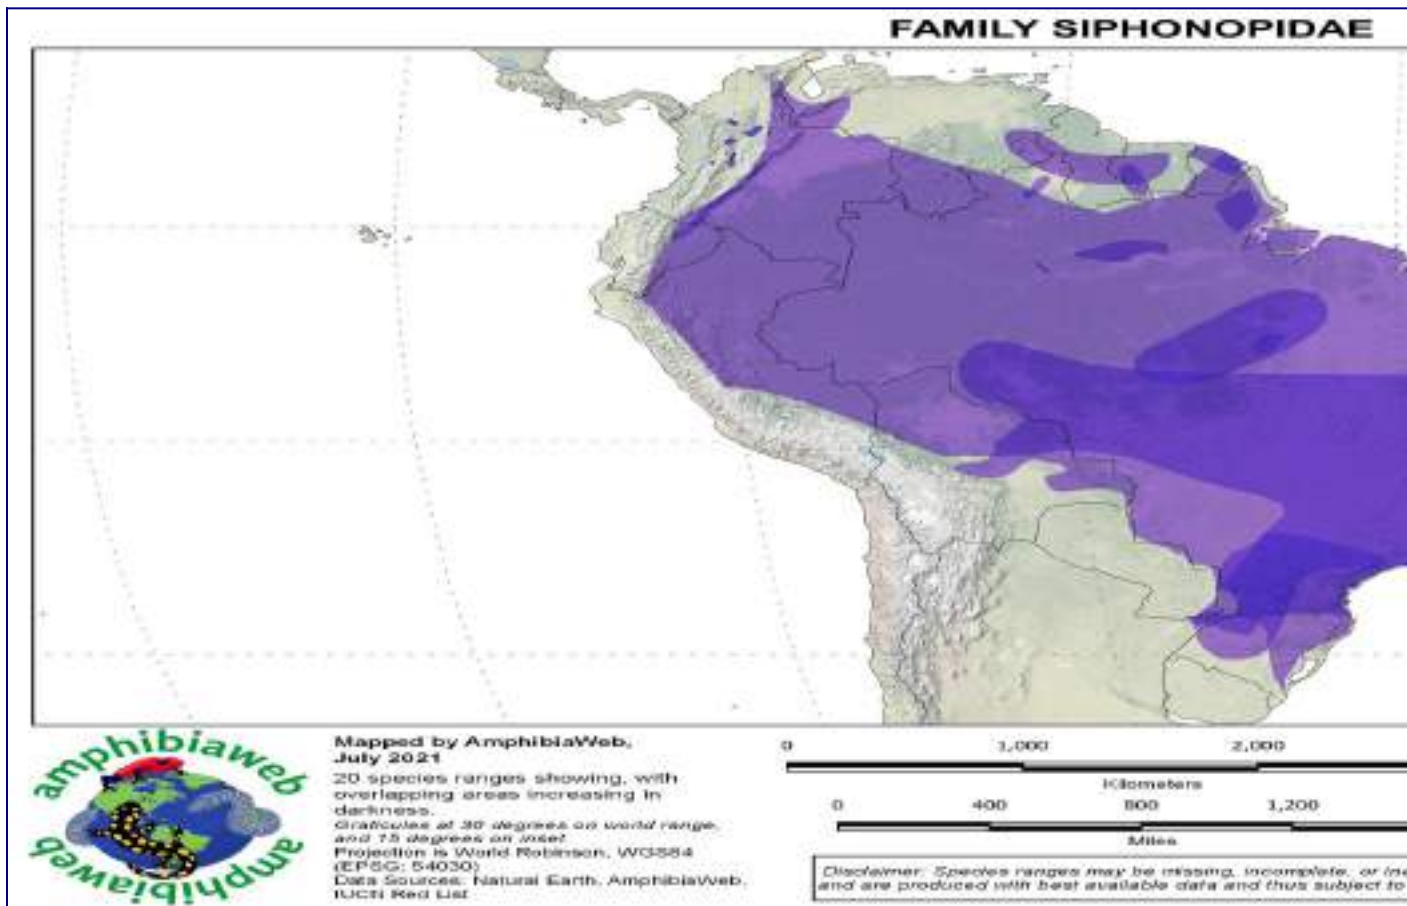

Written by AmphibiaWeb

### **Notable Family Characteristics**

- Fossorial
- Inhabits mostly tropical forests
- Oviparity

- Maternal dermatophagy, documented in some species but speculated to be in all
- Morphological characters include: 1) all with primary annuli, some with secondary, none with tertiary; inner mandibular teeth absent; 5) terminal shield present at caudal end of body but no true tail
- Distribution limited to South America

## Typhlonectidae

15 species in 5 genera

## ***Commonly Called Aquatic Caecilians***

Typhlonectids are unique among caecilians in that they are secondarily aquatic. Members range from 140-750 mm in length, with some species having scales as well as secondary annuli. One member of this family, *Atretochoana eiselti*, is the largest extant lungless caecilian.

This family is distributed in northern South America. The monophyly of this group is strongly supported through molecular data.

### **News Highlight**

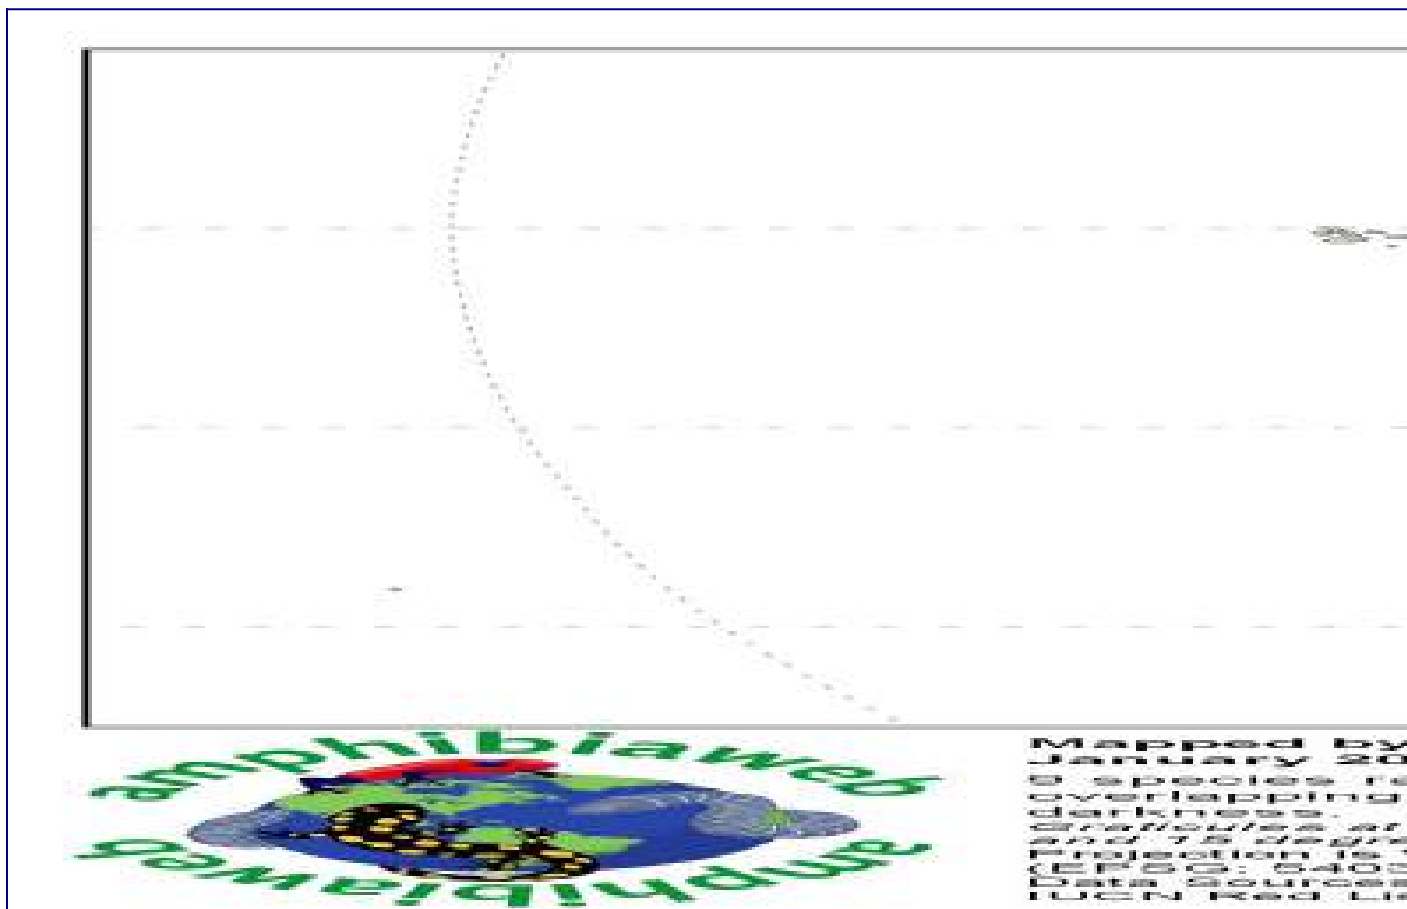

[Maciel et al. \(2016\)](#) analyze relationships of the semiaquatic and aquatic South American caecilians (Typhlonectidae) and propose new avenues of research questions about the evolutionary dynamics of the clade, such as examination of the role of the Amazon basin in the diversification of the group.

The caecilian fossil record is remarkably scarce. Although time-calibrated molecular phylogenies suggest a recent origin of the group, a fossilized caecilian was found in what was then a lake. The remarkable preservation of both its vertebral column and much of its skull is noteworthy.

Written by AmphibiaWeb

## **Notable Family Characteristics**

- Aquatic and Semi-aquatic
- Tropical and temperate forests
- Viviparous
- Morphological features include: 1) tracheal lungs and narial plugs; 2) secondary zygokrotaphic skulls;
- Fully aquatic species (*Typhlonectes*) have compressed bodies and dorsal fins
- Distribution limited to northern South America
